Abstract

In twistor theory, the canonical quantization procedure, called twistor quantization, is performed with the twistor operators represented as $\hat{Z}^A = Z^A \,(\in \mathbb{C})$ and $\hat{\bar{Z}}_A = -\frac{\partial}{\partial Z^A}$. However, it has not been clarified what kind of function spaces this representation is valid in. In the present paper, we try to find appropriate (pre-)Hilbert spaces in which the above representation is realized as an adjoint pair of operators. To this end, we define an inner product for the helicity eigenfunctions by an integral over the product space of the circular space S^1 and the upper half of projective twistor space. Using this inner product, we define a Hilbert space in some particular case and indefinite-metric pre-Hilbert spaces in other particular cases, showing that the above-mentioned representation is valid in these spaces. It is also shown that only the Penrose transform in the first particular case yields positive-frequency massless fields without singularities, while the Penrose transforms in the other particular cases yield positive-frequency massless fields with singularities.

Keywords: Twistor theory, Twistor quantization, Hilbert space, Penrose transform, Coherent state

1. Introduction

Twistor theory was first proposed by Penrose in 1967 as a novel approach to finding a unified framework for general relativity and quantum physics, aiming at establishing a theory of quantum gravity [1]. In twistor theory [2–8], a complex space called twistor space is considered to be a primary object for expressing physics, while 4-dimensional space-time is treated as a secondary object. One of the common motivations in early studies on twistor theory is thus to describe 4-dimensional space-time, gravity and even the elementary particles in an equal footing on the basis of the complex geometry of twistor space. Such an ambitious attempt in twistor theory has been summarized by Penrose himself as the *twistor programme* [7, 8].

Although twistor theory has provided various interesting ideas, it cannot be said that this theory has succeeded in physics in accordance with the twistor programme. From the viewpoint of physics, recent impressive progress related to twistor theory is only the discovery of a twistor string theory by Witten [9], which leads to the twistor approach to explaining scattering amplitudes in Yang-Mills theory [10, 11]. (An earlier twistor approach to Yang-Mills scattering amplitudes was considered by Nair [12].) On the other hand, twistor theory has yielded skillful geometrical tools for solving non-linear partial differential equations such as the anti-self-dual Yang-Mills equation [13, 14], the anti-self-dual equations for gravity [15] and the Bogomolny equation [16]. Also, there have been many other mathematical developments in twistor theory; see, e.g., Refs. [17–21].

It seems that one of the reasons why twistor theory has not developed well in physics and therefore the twistor programme has not been accomplished is that the quantum-theoretical framework of twistor theory has not yet been established sufficiently. In fact, in comparison with the standard quantum theory, mathematical settings such as Hilbert spaces have not been investigated satisfactorily in the canonical quantization procedure in twistor theory, called twistor quantization. To be precise, in twistor quantization, the twistor operators $\hat{Z}^A$ $(A = 0, 1, 2, 3)$ and their adjoint twistor operators $\hat{\bar{Z}}_A$ are naively represented as $\hat{Z}^A = Z^A$ and $\hat{\bar{Z}}_A = -\frac{\partial}{\partial Z^A}$, with the twistor variables $Z^A (\in \mathbb{C})$. However, it has not been clarified what kind of function spaces this representation is valid in. One of the main purposes of this paper is to find appropriate function spaces (or more precisely, appropriate (pre-)Hilbert spaces) in which the above representation holds true as an adjoint pair of operators.

Until now, there have been a few attempts to define Hilbert spaces in twistor quantization. In fact, Penrose gave an inner product of two holomorphic functions of Z^A that have the same degree of homogeneity [22]. With this inner product, Penrose defined a Hilbert space and showed that the representation $\hat{\bar{Z}}_A = -\frac{\partial}{\partial Z^A}$ is valid on this space. However, in his argument, the details on the inner product, such as the finiteness of the inner product, are unclear. Hence, there is room to doubt the presence of the Hilbert space. Penrose's inner product was modified by himself so that it can directly be derived from the scalar product between two massless fields in 4-dimensional space-time [23]. Even after the modification, $\hat{\bar{Z}}_A = -\frac{\partial}{\partial Z^A}$ holds, but the details on the inner product still remain unclear. Another kind of inner product, named the cohomological inner product, was defined by Müller for a restricted class of analytic functions of Z^A [24]. However, representations of the twistor operators are not considered in this approach.

In the present paper, we propose an alternative inner product of two holomorphic functions of Z^A. Here the two functions may have different degrees of homogeneity. To define the inner product, we first construct linear combinations of the $\hat{Z}^A$, denoted later by $\hat{a}^A$, and linear combinations of the $\hat{\bar{Z}}_A$, denoted later by $\hat{\bar{a}}^{\dot{A}}$, in such a manner that $\hat{a}^A$ and $\hat{\bar{a}}^{\dot{A}}$ satisfy a Weyl-Heisenberg algebra of indefinite-metric type. The commutation relations of this algebra are unitarily equivalent to what $\hat{Z}^A$ and $\hat{\bar{Z}}_A$ satisfy. Next, we provide a coherent state [25, 26] defined as a simultaneous eigenstate of the $\hat{\bar{a}}^{\dot{A}}$ and consider the helicity eigenvalue equation written in terms of $\hat{a}^A$ and $\hat{\bar{a}}^{\dot{A}}$. This equation can easily be solved in the coherent-state basis to obtain the helicity eigenvalues and their corresponding eigenfunctions. In the present paper, we assume that the holomorphic parts of the helicity eigenfunctions are transformed into positive-frequency massless fields in complexified Minkowski space via the Penrose transform [2–5]. (The holomorphic parts are precisely the so-called twistor functions.) This assumption is realized if the holomorphic parts are functions on the upper half of twistor space. Taking into account this fact, we define an inner product of two arbitrary helicity eigenfunctions by an integral over the product space of the circular space S^1 and the upper half of projective twistor space. (This inner product can also be regarded as the one defined for the corresponding holomorphic parts.) Carrying out the integration in the inner product, we obtain an expression that includes the orthogonality condition for the helicity eigenfunctions and a multiplicative factor consisting of gamma functions.

The multiplicative factor is evaluated by making use of the method of analytic continuation for the gamma function. We particularly examine the inner product for the helicity eigenfunctions each of whose holomorphic parts has singularities on two hyperplanes in twistor space. Such holomorphic parts are especially important in twistor theory from a practical viewpoint related to twistor diagrams [2, 23, 27–29]. It is then shown that the helicity eigenfunctions in a particular case can be normalized to unity, while the helicity eigenfunctions in other particular cases can be normalized to either 1 or -1.

In our approach, a Hilbert space for twistor quantization is defined as a set of the linear combinations of the helicity eigenfunctions in the first particular case mentioned above. In each of the other particular cases, it is possible to define an indefinite-metric pre-Hilbert space (or an indefinite inner product space) as a set of the finite linear combinations of the relevant helicity eigenfunctions. We show that the twistor operators represented as $\hat{Z}^A = Z^A$ and $\hat{\bar{Z}}_A = -\frac{\partial}{\partial Z^A} + \frac{1}{2}\bar{Z}_A$ are realized, in each of the (pre-)Hilbert spaces, as an adjoint pair of operators. Then, it is seen that $\hat{\bar{Z}}_A = -\frac{\partial}{\partial Z^A}$ is recognized as the adjoint operator of $\hat{Z}^A = Z^A$ by choosing the holomorphic parts of the helicity eigenfunctions to be basis functions, instead of the helicity eigenfunctions themselves. In this way, we can define (pre-)Hilbert spaces appropriate for twistor quantization.

We also perform the Penrose transforms [2–5] of twistor functions in each of the particular cases to find the corresponding positive-frequency massless fields in complexified Minkowski space. We point out that only the massless fields derived in the first particular case have no singularities, while those derived in the other particular cases have singularities.

The present paper is organized as follows. In Section 2, we briefly review twistor quantization by following popular literature on twistor theory. Section 3 provides a coherent state for twistor operators and gives the representation of twistor operators with respect to the coherent-state basis. In Section 4, we consider the helicity eigenvalue equation and solve it in the coherent-state basis. It is verified there that the helicity eigenfunctions are simultaneous eigenfunctions of the Cartan generators of $\mathrm{SU}(2,2)$. In Section 5, we propose an inner product defined for the helicity eigenfunctions and examine it in particular cases after using the method of analytic continuation for the gamma function. In Section 6, we define (pre-)Hilbert spaces in twistor quantization and show that the adjointness relations between twistor operators are valid in these spaces. In Section 7, we perform the Penrose transforms of the simplest twistor functions in each of the particular cases and investigate singularities of the massless fields derived by these transforms. Section 8 is devoted to a summary and discussion. Appendix A provides the Schwinger representation of the SU(2, 2) Lie algebra. Appendix B demonstrates the Penrose transform of a general twistor function in the first particular case.

2. Brief review of twistor quantization

In this section, we briefly review the twistor quantization procedure explained in Refs. [2, 3, 6–8].

Let Z^A $(A = 0, 1, 2, 3)$ be a twistor and $\bar{Z}_A$ its dual twistor. In terms of 2-component spinors, Z^A and $\bar{Z}_A$ are expressed as

$$Z^A = (\omega^\alpha, \pi_{\dot{\alpha}})\,, \qquad \bar{Z}_A = (\bar{\pi}_\alpha, \bar{\omega}^{\dot{\alpha}})\,, \tag{2.1}$$

where ω^α $(\alpha = 0, 1)$ and $\pi_{\dot{\alpha}}$ $(\dot{\alpha} = \dot{0}, \dot{1})$ are 2-component Weyl spinors, and $\bar{\omega}^{\dot{\alpha}}$ and $\bar{\pi}_\alpha$ are their complex conjugate spinors. The spinors ω^α and $\pi_{\dot{\alpha}}$ are related by $\omega^\alpha = iz^{\alpha\dot{\alpha}}\pi_{\dot{\alpha}}$, where the $z^{\alpha\dot{\alpha}}$ constitute coordinates of a point in complexified compactified Minkowski space $\mathbb{C}\mathbf{M}^\sharp$. (Here, $\mathbf{M}$ denotes 4-dimensional Minkowski space.) The space coordinatized by (Z^A) is called twistor space and is denoted by $\mathbf{T}$. The twistor space is a normed complex vector space with the pseudo-Hermitian norm squared $\bar{Z}_A Z^A$ of signature $(2, 2)$. With this norm squared, the helicity of a massless particle propagating in 4-dimensional Minkowski space $\mathbf{M}$ is simply represented as [1]

$$s = \frac{1}{2}\bar{Z}_A Z^A. \tag{2.2}$$

The conformal group of $\mathbf{M}$ is represented linearly in $\mathbf{T}$ as the linear group SU(2, 2) [32, 33]. Then, the conformal invariance of the helicity is evident from Eq. (2.2), because $\bar{Z}_A Z^A$ is invariant under the SU(2, 2) transformations. It can be said that twistors are SU(2, 2) spinors for the conformal group of $\mathbf{M}$.

In quantizing the classical system of twistors, Z^A and $\bar{Z}_A$ are replaced by the corresponding twistor operators $\hat{Z}^A$ and $\hat{\bar{Z}}_A$ satisfying the commutation relations

---

[1] The expression (2.2), as well as the commutation relations (2.3a) and (2.3b), can systematically be derived from the gauged Shirafuji action [30, 31].

$$\left[\hat{Z}^A, \hat{\bar{Z}}_B\right] = \delta^A_B\,, \tag{2.3a}$$

$$\left[\hat{Z}^A, \hat{Z}^B\right] = \left[\hat{\bar{Z}}_A, \hat{\bar{Z}}_B\right] = 0\,. \tag{2.3b}$$

So-called twistor quantization is carried out on the basis of the commutation relations (2.3a) and (2.3b). By analogy with standard quantum mechanics, we can naively take the representation in which $\hat{Z}^A$ reduces to Z^A:

$$\hat{Z}^A \doteq Z^A, \qquad \hat{\bar{Z}}_A \doteq -\frac{\partial}{\partial Z^A}. \tag{2.4}$$

(Here, the symbol $\doteq$ stands for gis represented byh.) This representation has actually been introduced in popular literature on twistor theory. A wave function appropriate for the representation (2.4) is to be holomorphic in Z^A. Such a wave function, $f(Z)$, is referred to as the twistor (wave) function. In the twistor quantization procedure, the helicity s is also treated as an operator. After having considered the Weyl ordering, the helicity operator reads

$$\hat{s} = \frac{1}{4}\left(\hat{\bar{Z}}_A\hat{Z}^A + \hat{Z}^A\hat{\bar{Z}}_A\right). \tag{2.5}$$

The eigenvalue equation $\hat{s}f = sf$ can be written in the representation (2.4) as

$$-\frac{1}{2}\left(Z^A\frac{\partial}{\partial Z^A} + 2\right)f(Z) = sf(Z)\,, \tag{2.6}$$

where s is understood as a helicity eigenvalue. Obviously, Eq. (2.6) is satisfied by a homogeneous twistor function of degree $-2s-2$. This degree must be an integer so that f can be a single-valued function on $\mathbf{T}$. In this way, s is restricted to integer and half-integer values.

3. A coherent state representation of twistor operators

From Eq. (2.1), we see that the complex conjugate of Z^A, i.e., $\bar{Z}^{\dot{A}} := \overline{Z^A}$ ($\dot{A} = \dot{0}, \dot{1}, \dot{2}, \dot{3}$), is related to $\bar{Z}_A$ by $\bar{Z}^{\dot{A}} = \bar{Z}_B J^{B\dot{A}}$, with the inverse metric $J^{A\dot{B}}$ on $\mathbf{T}$ defined by

$$\left(J^{A\dot{B}}\right) := \begin{pmatrix} 0 & I_2 \\ I_2 & 0 \end{pmatrix}. \tag{3.1}$$

Here, I_2 denotes the 2×2 unit matrix. In the twistor quantization procedure, $\bar{Z}^{\dot{A}}$ is replaced by the adjoint operator $\hat{\bar{Z}}^{\dot{A}} = \hat{\bar{Z}}_B J^{B\dot{A}}$ of $\hat{Z}^A$ satisfying $[\hat{Z}^A, \hat{\bar{Z}}^{\dot{B}}] = J^{A\dot{B}}$. (At present, the adjointness relation between $\hat{Z}^A$ and $\hat{\bar{Z}}^{\dot{A}}$ is just a formality.) This commutation relation is, of course, essential for twistor quantization. However, it is inconvenient for our analysis, because $(J^{A\dot{B}})$ is not a diagonal matrix. Desirable commutation relations are provided for the operators

$$\begin{aligned} \hat{a}^0 &:= \frac{1}{\sqrt{2}}\Big(\hat{Z}^0 + \hat{Z}^2\Big)\,, & \hat{a}^1 &:= \frac{1}{\sqrt{2}}\Big(\hat{Z}^1 + \hat{Z}^3\Big)\,, \\ \hat{a}^2 &:= \frac{1}{\sqrt{2}}\Big(-\hat{Z}^0 + \hat{Z}^2\Big)\,, & \hat{a}^3 &:= \frac{1}{\sqrt{2}}\Big(-\hat{Z}^1 + \hat{Z}^3\Big)\,, \end{aligned} \tag{3.2}$$

and their adjoint operators

$$\begin{aligned} \hat{\bar{a}}^{\dot{0}} &:= \frac{1}{\sqrt{2}}\Big(\hat{\bar{Z}}_0 + \hat{\bar{Z}}_2\Big)\,, & \hat{\bar{a}}^{\dot{1}} &:= \frac{1}{\sqrt{2}}\Big(\hat{\bar{Z}}_1 + \hat{\bar{Z}}_3\Big)\,, \\ \hat{\bar{a}}^{\dot{2}} &:= \frac{1}{\sqrt{2}}\Big(\hat{\bar{Z}}_0 - \hat{\bar{Z}}_2\Big)\,, & \hat{\bar{a}}^{\dot{3}} &:= \frac{1}{\sqrt{2}}\Big(\hat{\bar{Z}}_1 - \hat{\bar{Z}}_3\Big)\,. \end{aligned} \tag{3.3}$$

In fact, using the commutation relations (2.3a) and (2.3b), we can show that

$$\Big[\hat{a}^A, \hat{\bar{a}}^{\dot{B}}\Big] = I^{A\dot{B}}\,, \tag{3.4a}$$

$$\Big[\hat{a}^A, \hat{a}^B\Big] = \Big[\hat{\bar{a}}^{\dot{A}}, \hat{\bar{a}}^{\dot{B}}\Big] = 0\,, \tag{3.4b}$$

where $I^{A\dot{B}}$ is the diagonal inverse metric of the form $(I^{A\dot{B}}) = \mathrm{diag}(1, 1, -1, -1)$. From this, we see that $\mathbf{T}$ possesses the pseudo-Hermitian metric of signature $(2, 2)$, defined by $(I_{\dot{A}B}) = \mathrm{diag}(1, 1, -1, -1)$. The commutation relations (3.4a) and (3.4b) constitute a Weyl-Heisenberg algebra of indefinite-metric type.

Now, we construct a coherent state that is defined to be a simultaneous eigenstate of the operators $\hat{\bar{a}}^{\dot{A}}$. For this purpose, we first introduce the unitary operator [25]

$$\hat{U}(\alpha, \bar{\alpha}) := \exp\Big(\hat{\bar{a}}^{\dot{A}} I_{\dot{A}B} \alpha^B - \bar{\alpha}^{\dot{B}} I_{\dot{B}A} \hat{a}^A\Big)\,, \tag{3.5}$$

where the α^A are complex numbers and the $\bar{\alpha}^{\dot{A}}$ are their complex conjugates. The operator $\hat{U} = \hat{U}(\alpha, \bar{\alpha})$ generates translations of $\hat{a}^A$ and $\hat{\bar{a}}^{\dot{A}}$ in the following manner:

$$\hat{U}^{\dagger}\hat{a}^{A}\hat{U} = \hat{a}^{A} + \alpha^{A}\,, \qquad \hat{U}^{\dagger}\hat{\bar{a}}^{\dot{A}}\hat{U} = \hat{\bar{a}}^{\dot{A}} + \bar{\alpha}^{\dot{A}}\,. \tag{3.6}$$

We introduce the vacuum state $|\bar{0}\rangle$ specified by

$$\hat{\bar{a}}^{\dot{A}}|\bar{0}\rangle = 0\,, \quad \langle\bar{0}|\bar{0}\rangle = 1\,. \tag{3.7}$$

Then, it is readily verified that the vector $|\bar{\alpha}\rangle := \hat{U}|\bar{0}\rangle$ fulfills the eigenvalue equation $\hat{\bar{a}}^{\dot{A}}|\bar{\alpha}\rangle = \bar{\alpha}^{\dot{A}}|\bar{\alpha}\rangle$. This demonstrates that $|\bar{\alpha}\rangle$ is actually a coherent state for the operators $\hat{\bar{a}}^{\dot{A}}$. The normalization condition $\langle\bar{\alpha}|\bar{\alpha}\rangle = 1$ is guaranteed by the unitarity of $\hat{U}$. By using the Campbell-Baker-Hausdorff formula,[2] $|\bar{\alpha}\rangle$ can be expressed as

$$|\bar{\alpha}\rangle = \exp\!\left(\frac{1}{2}\|\alpha\|^2\right)\exp\!\left(-\bar{\alpha}^{\dot{A}}I_{\dot{A}B}\hat{a}^{B}\right)|\bar{0}\rangle\,, \tag{3.8}$$

where $\|\alpha\|^2 := \bar{\alpha}^{\dot{A}}I_{\dot{A}B}\alpha^{B} = |\alpha^0|^2 + |\alpha^1|^2 - |\alpha^2|^2 - |\alpha^3|^2$. We can also show that the dual vector $\langle\bar{\alpha}| = \langle\bar{0}|\hat{U}^{\dagger}$ satisfies [26]

$$\langle\bar{\alpha}|\hat{a}^{A} = \alpha^{A}\langle\bar{\alpha}|\,, \tag{3.9a}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{A}} = \left(-\frac{\partial}{\partial\alpha^{B}}I^{B\dot{A}} + \frac{1}{2}\bar{\alpha}^{\dot{A}}\right)\langle\bar{\alpha}|\,. \tag{3.9b}$$

The complex numbers α^{A} and the twistor variables $Z^{A} = (\omega^{\alpha}, \pi_{\dot{\alpha}})$ are related by the relations that are obtained by replacing $\hat{a}^{A}$ and $\hat{Z}^{A}$ in Eq, (3.2) with α^{A} and Z^{A}, respectively:

$$\begin{aligned} \alpha^0 &= \frac{1}{\sqrt{2}}\left(Z^0 + Z^2\right), \qquad & \alpha^1 &= \frac{1}{\sqrt{2}}\left(Z^1 + Z^3\right), \\ \alpha^2 &= \frac{1}{\sqrt{2}}\left(-Z^0 + Z^2\right), \qquad & \alpha^3 &= \frac{1}{\sqrt{2}}\left(-Z^1 + Z^3\right), \end{aligned} \tag{3.10}$$

or equivalently,

$$\begin{aligned} \alpha^0 &= \frac{1}{\sqrt{2}}\left(\omega^0 + \pi_{\dot{0}}\right), \qquad & \alpha^1 &= \frac{1}{\sqrt{2}}\left(\omega^1 + \pi_{\dot{1}}\right), \\ \alpha^2 &= \frac{1}{\sqrt{2}}\left(-\omega^0 + \pi_{\dot{0}}\right), \qquad & \alpha^3 &= \frac{1}{\sqrt{2}}\left(-\omega^1 + \pi_{\dot{1}}\right). \end{aligned} \tag{3.11}$$

---

[2] When the operators X and Y commute with $[X,Y]$, the Campbell-Baker-Hausdorff formula reads $e^{X+Y} = e^{X}e^{Y}e^{-\frac{1}{2}[X,Y]}$.

With these relations, it is easy to see that $\|\alpha\|^2 = \bar{Z}_A Z^A = \bar{\pi}_\alpha \omega^\alpha + \bar{\omega}^{\dot{\alpha}} \pi_{\dot{\alpha}}$. Since α^A relate to Z^A by a unitary transformation specified by Eq. (3.10), we may call α^A a twistor (defined with respect to another basis of $\mathbf{T}$). Correspondingly, we may call $\hat{a}^A$ and $\hat{\bar{a}}^{\dot{A}}$ twistor operators.

In terms of the twistor variables Z^A and $\bar{Z}_A$ and their corresponding operators, Eq. (3.9) can be written as

$$\langle \bar{Z} | \hat{Z}^A = Z^A \langle \bar{Z} | \,, \quad \langle \bar{Z} | \hat{\bar{Z}}_A = \left(-\frac{\partial}{\partial Z^A} + \frac{1}{2} \bar{Z}_A \right) \langle \bar{Z} | \,, \tag{3.12}$$

where $\langle \bar{Z} | := \langle \bar{0} | \exp\bigl(-\hat{\bar{Z}}_A Z^A \bigr) \exp\bigl(\tfrac{1}{2} \bar{Z}_A Z^A \bigr) \; (= \langle \bar{\alpha} |)$. Apart from the additive factor $\frac{1}{2}\bar{Z}_A$, Eq. (3.12) leads to the representation given in Eq. (2.4). If $\langle \bar{Z} |$ is defined by $\langle \bar{Z} | = \langle \bar{0} | \exp\bigl(- \hat{\bar{Z}}_A Z^A \bigr)$ without the multiplicative factor $\exp\bigl(\tfrac{1}{2} \bar{Z}_A Z^A \bigr)$, we have $\langle \bar{Z} | \hat{\bar{Z}}_A = -\partial \langle \bar{Z} | / \partial Z^A$, and hence immediately find Eq. (2.4). However, in general, this $\langle \bar{Z} |$ is not a unit vector, because it satisfies $\langle \bar{Z} | \bar{Z} \rangle = \exp\bigl(- \bar{Z}_A Z^A \bigr)$.

4. Simultaneous eigenfunctions for the helicity operator and the Cartan generators of SU(2, 2)

The procedure in the previous section is a mere formality at present, because function spaces in which Eq. (3.9) is realized are still unclear. Therefore we now try to find functions suitable for defining desirable function spaces that can be shown to be (pre-)Hilbert spaces.

In terms of $\hat{a}^A$ and $\hat{\bar{a}}^{\dot{A}}$, the helicity operator (2.5) can be written as

$$\begin{aligned} \hat{s} &= \frac{1}{4} \Bigl(\hat{\bar{a}}^{\dot{A}} I_{\dot{A}B} \hat{a}^B + \hat{a}^B \hat{\bar{a}}^{\dot{A}} I_{\dot{A}B} \Bigr) \\ &= \frac{1}{2} \Bigl(\hat{\bar{a}}^{\dot{0}} \hat{a}^0 + \hat{\bar{a}}^{\dot{1}} \hat{a}^1 - \hat{\bar{a}}^{\dot{2}} \hat{a}^2 - \hat{\bar{a}}^{\dot{3}} \hat{a}^3 \Bigr) + 1 \,. \end{aligned} \tag{4.1}$$

With this form of $\hat{s}$, we consider the helicity eigenvalue equation

$$\hat{s} | \Phi \rangle = s | \Phi \rangle \,, \tag{4.2}$$

where s is a helicity eigenvalue and $|\Phi\rangle$ is its corresponding helicity eigenvector. Multiplying both sides of Eq. (4.2) by $\langle \bar{\alpha} |$ on the left and using Eq. (3.9), we have

$$\left(\alpha^A \frac{\partial}{\partial \alpha^A} - \frac{1}{2} \|\alpha\|^2 \right) \Phi(\alpha) = (-2s - 2) \Phi(\alpha) \,, \tag{4.3}$$

where $\mathit{\Phi}(\alpha)$ is the helicity eigenfunction defined by $\mathit{\Phi}(\alpha) := \langle \bar{\alpha} | \mathit{\Phi} \rangle$. This equation can easily be solved to yield the particular solution

$$\mathit{\Phi}_{k,l,m,n}(\alpha) = f_{k,l,m,n}(\alpha) \exp\left(\frac{1}{2} \|\alpha\|^2 \right) , \tag{4.4}$$

with the holomorphic function

$$f_{k,l,m,n}(\alpha) := C_{k,l,m,n} (\alpha^0)^k (\alpha^1)^l (\alpha^2)^m (\alpha^3)^n . \tag{4.5}$$

Here, $C_{k,l,m,n}$ is an undetermined coefficient, and k, l, m and n are constants satisfying

$$s = -\frac{1}{2}(k + l + m + n) - 1 . \tag{4.6}$$

Clearly, $f_{k,l,m,n}$ is a homogeneous twistor function of degree $-2s - 2$. The single-valuedness of $\mathit{\Phi}_{k,l,m,n}$, or equivalently that of $f_{k,l,m,n}$, is valid if and only if k, l, m and n are integers. Then, from Eq. (4.6), the helicity eigenvalue s is determined to take integer and half-integer values. The helicity of a massless particle is thus quantized as a result of twistor quantization.

Now, we note that the helicity operator $\hat{s}$ commutes with all the generators of SU$(2, 2)$ represented as Eq. (A.6); see Appendix A. The Lie group SU$(2, 2)$ has rank 3, and in the Schwinger representation (A.6), its Cartan generators are given by

$$\begin{aligned} \hat{\mathit{\Lambda}}_3 &= \frac{1}{2}\left(\hat{\bar{a}}^{\dot{0}} \hat{a}^0 - \hat{\bar{a}}^{\dot{1}} \hat{a}^1 \right) , \quad \hat{\mathit{\Lambda}}_6 = -\frac{1}{2}\left(\hat{\bar{a}}^{\dot{2}} \hat{a}^2 - \hat{\bar{a}}^{\dot{3}} \hat{a}^3 \right) , \\ \hat{\mathit{\Lambda}}_{15} &= \frac{1}{2\sqrt{2}}\left(\hat{\bar{a}}^{\dot{0}} \hat{a}^0 + \hat{\bar{a}}^{\dot{1}} \hat{a}^1 + \hat{\bar{a}}^{\dot{2}} \hat{a}^2 + \hat{\bar{a}}^{\dot{3}} \hat{a}^3 \right) . \end{aligned} \tag{4.7}$$

Because $\hat{s}$, $\hat{\mathit{\Lambda}}_3$, $\hat{\mathit{\Lambda}}_6$, and $\hat{\mathit{\Lambda}}_{15}$ commute with each other, they have a simultaneous eigenfunction $\mathit{\Phi}(\alpha)$ satisfying

$$\langle \bar{\alpha} | \hat{s} | \mathit{\Phi} \rangle = s \mathit{\Phi}(\alpha) , \tag{4.8a}$$

$$\langle \bar{\alpha} | \hat{\mathit{\Lambda}}_3 | \mathit{\Phi} \rangle = K \mathit{\Phi}(\alpha) , \tag{4.8b}$$

$$\langle \bar{\alpha} | \hat{\mathit{\Lambda}}_6 | \mathit{\Phi} \rangle = L \mathit{\Phi}(\alpha) , \tag{4.8c}$$

$$\langle \bar{\alpha} | \hat{\mathit{\Lambda}}_{15} | \mathit{\Phi} \rangle = \frac{1}{\sqrt{2}} M \mathit{\Phi}(\alpha) , \tag{4.8d}$$

where s, K, L and $M/\sqrt{2}$ are eigenvalues of $\hat{s}$, $\hat{\mathit{\Lambda}}_3$, $\hat{\mathit{\Lambda}}_6$ and $\hat{\mathit{\Lambda}}_{15}$, respectively. (Equation (4.8a) is identical with Eq. (4.2) multiplied by $\langle\bar{\alpha}|$.) Using Eq. (3.9), we can show that $\mathit{\Phi}_{k,l,m,n}(\alpha)$ is a solution of the simultaneous equations (4.8a)-(4.8d) provided that Eq. (4.6) and

$$K = \frac{1}{2}(-k + l)\,, \quad L = \frac{1}{2}(-m + n)\,, \quad M = \frac{1}{2}(-k - l + m + n) \tag{4.9}$$

are fulfilled. In this way, $\mathit{\Phi}_{k,l,m,n}$ is confirmed to be a simultaneous eigenfunction for $\hat{s}$, $\hat{\mathit{\Lambda}}_3$, $\hat{\mathit{\Lambda}}_6$ and $\hat{\mathit{\Lambda}}_{15}$. From Eq. (4.9), it follows that K, L, M, as well as s, take integer and half-integer values. The set of Eqs. (4.6) and (4.9) can inversely be solved as

$$\begin{aligned} k &= -\frac{1}{2}(s + 2K + M + 1)\,, \qquad l = \frac{1}{2}(-s + 2K - M - 1)\,, \\ m &= -\frac{1}{2}(s + 2L - M + 1)\,, \qquad n = \frac{1}{2}(-s + 2L + M - 1)\,. \end{aligned} \tag{4.10}$$

This fact demonstrates that the combination of eigenvalues $(s, K, L, M/\sqrt{2}\,)$ is in bijective correspondence with the combination of integers (k, l, m, n). For this reason, we can use (s, K, L, M) to uniquely specify the simultaneous eigenfunction $\mathit{\Phi}_{k,l,m,n}$, which fact enables us to denote $\mathit{\Phi}_{k,l,m,n}$ as $\mathit{\Phi}_{s,K,L,M}$, and correspondingly $f_{k,l,m,n}$ as $f_{s,K,L,M}$, namely

$$\mathit{\Phi}_{s,K,L,M} := \mathit{\Phi}_{k,l,m,n}\,, \qquad f_{s,K,L,M} := f_{k,l,m,n}\,. \tag{4.11}$$

The helicity eigenvalue s labels an irreducible representation of SU$(2,2)$. This can be understood from the fact that the eigenvalue of the quadratic Casimir operator of SU$(2,2)$ is determined to be $3(s^2 - 1)/2$, as seen from Eq. (A.10) in Appendix A. The eigenfunction $\mathit{\Phi}_{s,K,L,M}$ is classified into the irreducible representation of SU$(2,2)$ labeled by s and is completely specified by the remaining eigenvalues K, L, and M [32].

Now, we consider application of the operators $\hat{a}^A$ to $\mathit{\Phi}_{k,l,m,n}$. This can be evaluated by using Eq. (3.9a) as follows:

$$\langle\bar{\alpha}|\hat{a}^0|\varPhi_{k,l,m,n}\rangle = \alpha^0\varPhi_{k,l,m,n}(\alpha) = \frac{C_{k,l,m,n}}{C_{k+1,l,m,n}}\varPhi_{k+1,l,m,n}(\alpha)\,, \tag{4.12a}$$

$$\langle\bar{\alpha}|\hat{a}^1|\varPhi_{k,l,m,n}\rangle = \alpha^1\varPhi_{k,l,m,n}(\alpha) = \frac{C_{k,l,m,n}}{C_{k,l+1,m,n}}\varPhi_{k,l+1,m,n}(\alpha)\,, \tag{4.12b}$$

$$\langle\bar{\alpha}|\hat{a}^2|\varPhi_{k,l,m,n}\rangle = \alpha^2\varPhi_{k,l,m,n}(\alpha) = \frac{C_{k,l,m,n}}{C_{k,l,m+1,n}}\varPhi_{k,l,m+1,n}(\alpha)\,, \tag{4.12c}$$

$$\langle\bar{\alpha}|\hat{a}^3|\varPhi_{k,l,m,n}\rangle = \alpha^3\varPhi_{k,l,m,n}(\alpha) = \frac{C_{k,l,m,n}}{C_{k,l,m,n+1}}\varPhi_{k,l,m,n+1}(\alpha)\,. \tag{4.12d}$$

Also, using Eq. (3.9b), we can evaluate application of the operators $\hat{\bar{a}}^{\dot{A}}$ to $\varPhi_{k,l,m,n}$:

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{0}}|\varPhi_{k,l,m,n}\rangle = -e^{\|\alpha\|^2/2}\frac{\partial f_{k,l,m,n}}{\partial\alpha^0} = -\frac{C_{k,l,m,n}}{C_{k-1,l,m,n}}k\varPhi_{k-1,l,m,n}(\alpha)\,, \tag{4.13a}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{1}}|\varPhi_{k,l,m,n}\rangle = -e^{\|\alpha\|^2/2}\frac{\partial f_{k,l,m,n}}{\partial\alpha^1} = -\frac{C_{k,l,m,n}}{C_{k,l-1,m,n}}l\varPhi_{k,l-1,m,n}(\alpha)\,, \tag{4.13b}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{2}}|\varPhi_{k,l,m,n}\rangle = e^{\|\alpha\|^2/2}\frac{\partial f_{k,l,m,n}}{\partial\alpha^2} = \frac{C_{k,l,m,n}}{C_{k,l,m-1,n}}m\varPhi_{k,l,m-1,n}(\alpha)\,, \tag{4.13c}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{3}}|\varPhi_{k,l,m,n}\rangle = e^{\|\alpha\|^2/2}\frac{\partial f_{k,l,m,n}}{\partial\alpha^3} = \frac{C_{k,l,m,n}}{C_{k,l,m,n-1}}n\varPhi_{k,l,m,n-1}(\alpha)\,. \tag{4.13d}$$

It is seen from Eqs. (4.12) and (4.13) that the $\hat{a}^A$ behave as creation operators, while the $\hat{\bar{a}}^{\dot{A}}$ behave as annihilation operators.

5. An appropriate inner product for the eigenfunctions $\boldsymbol{\varPhi_{s,K,L,M}}$

If we follow the argument of coherent states [25, 26], it is quite natural to naively define the inner product of two arbitrary eigenfunctions, $\varPhi_{s,K,L,M}$ and $\varPhi_{s',K',L',M'}$, as

$$\begin{aligned}
&\langle\varPhi_{s,K,L,M}|\varPhi_{s',K',L',M'}\rangle_{\text{naive}} \\
&:= \int_{\mathbf{T}} \overline{\varPhi_{s,K,L,M}(\alpha)}\,\varPhi_{s',K',L',M'}(\alpha)\,d^8\mu(\alpha,\bar{\alpha}) \\
&\ = \int_{\mathbf{T}} \overline{f_{s,K,L,M}(\alpha)}\,f_{s',K',L',M'}(\alpha)\exp\|\alpha\|^2 d^8\mu(\alpha,\bar{\alpha})\,,
\end{aligned} \tag{5.1}$$

where

$$d^8\mu(\alpha, \bar{\alpha}) := d\alpha^0 \wedge d\alpha^1 \wedge d\alpha^2 \wedge d\alpha^3 \wedge d\bar{\alpha}^{\dot{0}} \wedge d\bar{\alpha}^{\dot{1}} \wedge d\bar{\alpha}^{\dot{2}} \wedge d\bar{\alpha}^{\dot{3}} \,. \tag{5.2}$$

Obviously, $d^8\mu$ is invariant under SU(2, 2) transformations. Although Eq. (5.1) might seem to be well-defined, actually, $\langle \mathit{\Phi}_{s,K,L,M} | \mathit{\Phi}_{s,K,L,M} \rangle_{\text{naive}}$ diverges because the integrand contains the multiplicative factor $\exp(|\alpha^0|^2 + |\alpha^1|^2)$, which strictly increases fast as $|\alpha^0| \to \infty$ or as $|\alpha^1| \to \infty$. Hence, the inner product (5.1) is not well-defined and we cannot use it in our approach.

Before providing an appropriate inner product, we recall that in twistor theory, *projective twistors* are considered to be more essential than twistors themselves. From this point of view, it is sufficient to define an inner product of $\mathit{\Phi}_{s,K,L,M}$ and $\mathit{\Phi}_{s',K',L',M'}$ in such a manner that projective twistors are taken to be integration variables. For a nonzero twistor α^A, the projective twistor $[\alpha^A]$ is defined as the proportionality class $[\alpha^A] := \big\{ \upsilon\alpha^A \big| \, \upsilon \in \mathbb{C} \setminus \{0\} \big\}$. The projective twistor space $\mathbf{PT} (\cong \mathbb{C}\mathbf{P}^3)$ is a 3-dimensional complex space coordinatized by $[(\alpha^A)] := \big\{ (\upsilon\alpha^A) \big| \, \upsilon \in \mathbb{C} \setminus \{0\} \big\}$, that is, $\mathbf{PT} := \big\{ [(\alpha^A)] \, \big| \, (\alpha^A) \in \mathbf{T} \setminus \{\mathbf{0}\} \big\}$. Clearly, the projective twistor $[\alpha^A]$ is invariant under the complexified scale transformation $\alpha^A \to \upsilon\alpha^A$, and hence the functions of $[\alpha^A]$ remain invariant under this transformation. Conversely, the functions of α^A that are invariant under the complexified scale transformation can be treated as functions of $[\alpha^A]$, that is, functions on $\mathbf{PT}$. Similarly, the functions of α^A that are invariant under the (pure) scale transformation $\alpha^A \to |\upsilon|\alpha^A$ can be treated as functions on $S^1 \times \mathbf{PT}$. Here, S^1 denotes the circular space parametrized by a phase common to the twistor variables.

Now, we assume that the twistor functions $f_{s,K,L,M}$ and $f_{s',K',L',M'}$ are transformed into positive-frequency massless fields in complexified Minkowski space $\mathbb{C}\mathbf{M}$ via the Penrose transform [2–5]. In this case, $f_{s,K,L,M}$ and $f_{s',K',L',M'}$ are realized as functions on the upper half of twistor space, namely $\mathbf{T}^+ := \big\{ (\alpha^A) \in \mathbf{T} \, \big| \, \|\alpha\|^2 > 0 \big\}$. Considering this, we propose the following inner product:

$$
\begin{aligned}
&\langle \mathit{\Phi}_{s,K,L,M} | \mathit{\Phi}_{s',K',L',M'} \rangle \\
&:= \lim_{\epsilon \to +0} \frac{-\epsilon}{\mathit{\Gamma}(s+s'+2\epsilon-1)} \int_{S^1 \times \mathbf{PT}^+} \overline{\mathit{\Phi}_{s+\epsilon,K,L,M}(\alpha)}\, \mathit{\Phi}_{s'+\epsilon,K',L',M'}(\alpha) \\
&\qquad \times \big(\|\alpha\|^2\big)^{s+s'+2\epsilon+2} \exp\big(-\|\alpha\|^2\big)\, d^7\mu(\alpha,\bar{\alpha}) \qquad (5.3\text{a}) \\
&= \lim_{\epsilon \to +0} \frac{-\epsilon}{\mathit{\Gamma}(s+s'+2\epsilon-1)} \int_{S^1 \times \mathbf{PT}^+} \overline{f_{s+\epsilon,K,L,M}(\alpha)}\, f_{s'+\epsilon,K',L',M'}(\alpha) \\
&\qquad \times \big(\|\alpha\|^2\big)^{s+s'+2\epsilon+2} d^7\mu(\alpha,\bar{\alpha})\,, \qquad (5.3\text{b})
\end{aligned}
$$

with the 7-form

$$
\begin{aligned}
&d^7\mu(\alpha,\bar{\alpha}) \\
&:= \frac{1}{12\big(\|\alpha\|^2\big)^4} \Big(d\alpha^0 \wedge d\alpha^1 \wedge d\alpha^2 \wedge d\alpha^3 \wedge \varepsilon_{\dot{A}\dot{B}\dot{C}\dot{D}} \bar{\alpha}^{\dot{A}} d\bar{\alpha}^{\dot{B}} \wedge d\bar{\alpha}^{\dot{C}} \wedge d\bar{\alpha}^{\dot{D}} \\
&\qquad + \varepsilon_{ABCD} \alpha^A d\alpha^B \wedge d\alpha^C \wedge d\alpha^D \wedge d\bar{\alpha}^{\dot{0}} \wedge d\bar{\alpha}^{\dot{1}} \wedge d\bar{\alpha}^{\dot{2}} \wedge d\bar{\alpha}^{\dot{3}} \Big)\,, \qquad (5.4)
\end{aligned}
$$

where $\mathbf{PT}^+ := \big\{ [(\alpha^A)] \in \mathbf{PT} \,\big|\, \|\alpha\|^2 > 0 \big\}$, and $\varepsilon_{0123} = \varepsilon_{\dot{0}\dot{1}\dot{2}\dot{3}} = 1$. The integrand $\overline{f_{s,K,L,M}(\alpha)}\, f_{s',K',L',M'}(\alpha) \big(\|\alpha\|^2\big)^{s+s'+2}$ can be regarded as a function on the product space $S^1 \times \mathbf{PT}^+$,[3] because it remains invariant under the (pure) scale transformation $\alpha^A \to |\upsilon| \alpha^A$, and also $f_{s,K,L,M}$ and $f_{s',K',L',M'}$ are functions on $\mathbf{T}^+$. (When $s = s'$, this integrand remains invariant under the complexified scale transformation $\alpha^A \to \upsilon \alpha^A$ and therefore is treated as a function on $\mathbf{PT}^+$.) Adding the infinitesimal positive number ϵ to s and s' is necessary for making Eq. (5.3) well-defined. The 7-form $d^7\mu$ is invariant under SU(2, 2) transformations and under the complexified scale transformation; thus, $d^7\mu$ is recognized as an integration measure on $S^1 \times \mathbf{PT}^+$. From the facts stated above, it is clear that the inner product $\langle \mathit{\Phi}_{s,K,L,M} | \mathit{\Phi}_{s',K',L',M'} \rangle$ is invariant under the (pure) scale transformation.

To see more precisely that $d^7\mu$ is an integration measure on $S^1 \times \mathbf{PT}^+$, here we introduce the inhomogeneous coordinates $(\zeta^1, \zeta^2, \zeta^3)$ of $\mathbf{PT}^+$ defined by [4]

---

[3] The projective twistor subspace $\mathbf{PT}^+$ is isomorphic to the coset space $\mathrm{SU}(2,2)/\mathrm{S}\big(\mathrm{U}(2,1) \times \mathrm{U}(1)\big)$ [34]. Similarly, $S^1 \times \mathbf{PT}^+$ is isomorphic to $\mathrm{SU}(2,2)/\mathrm{SU}(2,1)$.

$$\zeta^1 := \frac{\alpha^1}{\alpha^0}\,, \quad \zeta^2 := \frac{\alpha^2}{\alpha^0}\,, \quad \zeta^3 := \frac{\alpha^3}{\alpha^0}\,. \tag{5.5}$$

With these coordinates, $d^7\mu$ can be expressed as

$$d^7\mu = d\theta \wedge d^6\mu\,, \tag{5.6}$$

where θ is the phase common to the twistor variables

$$\theta := -\frac{1}{4} i \log\left(\prod_{A=0}^{3} \frac{\alpha^A}{|\alpha^A|}\right) = -i \log\left(\frac{\alpha^0}{|\alpha^0|}\right) - \frac{1}{4} i \log\left(\prod_{A=1}^{3} \frac{\zeta^A}{|\zeta^A|}\right). \tag{5.7}$$

The range of θ is determined to be $[0, 2\pi)$. The 6-form $d^6\mu$ is given by

$$d^6\mu := \frac{i}{K^4} d\zeta^1 \wedge d\zeta^2 \wedge d\zeta^3 \wedge d\bar{\zeta}^{\dot{1}} \wedge d\bar{\zeta}^{\dot{2}} \wedge d\bar{\zeta}^{\dot{3}}\,, \tag{5.8}$$

with $K := 1 + |\zeta^1|^2 - |\zeta^2|^2 - |\zeta^3|^2$. The 6-form $d^6\mu$ is precisely the volume element of $\mathbf{PT}^+$.[5] In this way, Eq. (5.6) demonstrates that $d^7\mu$ is indeed an integration measure on $S^1 \times \mathbf{PT}^+$.

For evaluating the inner product (5.3), it is convenient to use the hyperbolic polar coordinates $(\|\alpha\|, \eta, \chi, \psi, \theta, \vartheta, \phi, \varphi)$ defined by $\|\alpha\| := \sqrt{\|\alpha\|^2}$ and

$$\alpha^0 = \|\alpha\| e^{i(\theta+\vartheta+\phi)} \cosh\eta \cos\chi\,, \tag{5.9a}$$

$$\alpha^1 = \|\alpha\| e^{i(\theta+\vartheta-\phi)} \cosh\eta \sin\chi\,, \tag{5.9b}$$

$$\alpha^2 = \|\alpha\| e^{i(\theta-\vartheta+\varphi)} \sinh\eta \cos\psi\,, \tag{5.9c}$$

$$\alpha^3 = \|\alpha\| e^{i(\theta-\vartheta-\varphi)} \sinh\eta \sin\psi\,. \tag{5.9d}$$

Here, by virtue of $\|\alpha\|^2 > 0$, it follows that $\|\alpha\|$ takes values in the coordinate range $0 < \|\alpha\| < \infty$. The other coordinate ranges are determined to be

$$0 \le \eta < \infty\,, \quad 0 \le \chi, \psi \le \frac{\pi}{2}\,, \quad 0 \le \theta < 2\pi\,, \quad -\pi < \vartheta, \phi, \varphi < \pi\,. \tag{5.10}$$

---

[4] Strictly speaking, $(\zeta^1, \zeta^2, \zeta^3)$ is a local coordinate system on the open set $\mathbf{PT}_0^+ := \big\{[(\alpha^A)] \in \mathbf{PT}^+ \,\big|\, \alpha^0 \neq 0\big\}$.

[5] The volume element $d^6\mu$ can be derived from the Kähler form $\mathit{\Omega} := i\partial\bar{\partial}\log K$ as $d^6\mu = \frac{1}{3!}\mathit{\Omega} \wedge \mathit{\Omega} \wedge \mathit{\Omega}$ [35, 36]. The Kähler form $\mathit{\Omega}$ itself is independent of the choice of local coordinate system, so that $d^6\mu$ is also coordinate independent.

Equations (5.9) and (5.10) can be found through the polar decomposition $\alpha^A = |\alpha^A| e^{i\theta_A}$ $(0 \leq |\alpha^A| < \infty,\ 0 \leq \theta_A < 2\pi)$. In the hyperbolic polar coordinate system, $d^7\mu$ is expressed as

$$d^7\mu = d\theta \wedge 2(\sinh 2\eta)^3 \sin 2\chi \sin 2\psi \, d\eta \wedge d\chi \wedge d\psi \wedge d\vartheta \wedge d\phi \wedge d\varphi \,. \tag{5.11}$$

Substituting Eqs. (5.9) and (5.11) into Eq. (5.3b) and carrying out the integration over $S^1 \times \mathbf{PT}^+$, we obtain

$$\begin{aligned} &\langle \mathit{\Phi}_{s,K,L,M} | \mathit{\Phi}_{s',K',L',M'} \rangle \\ &= \frac{1}{2}(4\pi)^4 |C_{s,K,L,M}|^2 \delta_{ss'} \delta_{KK'} \delta_{LL'} \delta_{MM'} \\ &\quad \times \lim_{\epsilon \to +0} \frac{-\epsilon}{\mathit{\Gamma}(s+M+\epsilon)\mathit{\Gamma}(-s-M+1-\epsilon)} \\ &\quad \times \mathit{\Gamma}\left(\frac{-s+2K-M+1-\epsilon}{2}\right) \mathit{\Gamma}\left(\frac{-s-2K-M+1-\epsilon}{2}\right) \\ &\quad \times \mathit{\Gamma}\left(\frac{-s+2L+M+1-\epsilon}{2}\right) \mathit{\Gamma}\left(\frac{-s-2L+M+1-\epsilon}{2}\right). \end{aligned} \tag{5.12}$$

Here, the integration formulas

$$\int_0^\infty (\sinh\eta)^{2x-1} (\cosh\eta)^{2y-1} d\eta = \frac{\mathit{\Gamma}(x)\mathit{\Gamma}(-x-y+1)}{2\mathit{\Gamma}(-y+1)} \,, \qquad \Re(x) > 0 \,,\ \Re(x+y) < 1 \,, \tag{5.13a}$$

$$\int_0^{\pi/2} (\sin\chi)^{2x-1} (\cos\chi)^{2y-1} d\chi = \frac{\mathit{\Gamma}(x)\mathit{\Gamma}(y)}{2\mathit{\Gamma}(x+y)} \,, \qquad \Re(x) > 0 \,,\ \Re(y) > 0 \tag{5.13b}$$

have been used. Also, an analytic continuation of the gamma function $\mathit{\Gamma}(2s + 2\epsilon - 1)$ that occurs in calculating the inner product has been considered. The orthogonality denoted by $\delta_{ss'}$ has been found by the integration over S^1; thus, $\langle \mathit{\Phi}_{s,K,L,M} | \mathit{\Phi}_{s,K',L',M'} \rangle$, the inner product restricted within the subspace specified by s, turns out to be given as an integral over $\mathbf{PT}^+$. In terms of (k, l, m, n), Eq. (5.12) can be written as

$$\begin{aligned} &\langle \mathit{\Phi}_{k,l,m,n} | \mathit{\Phi}_{k',l',m',n'} \rangle \\ &= (4\pi)^4 |C_{k,l,m,n}|^2 \delta_{kk'} \delta_{ll'} \delta_{mm'} \delta_{nn'} \\ &\quad \times \lim_{\varepsilon \to +0} \frac{-\varepsilon \mathit{\Gamma}(k+1-\varepsilon)\mathit{\Gamma}(l+1-\varepsilon)\mathit{\Gamma}(m+1-\varepsilon)\mathit{\Gamma}(n+1-\varepsilon)}{\mathit{\Gamma}(-k-l-1+2\varepsilon)\mathit{\Gamma}(k+l+2-2\varepsilon)} \,, \end{aligned} \tag{5.14}$$

where $\varepsilon := \epsilon/2$. In deriving Eqs (5.12) and (5.14), the arguments of the gamma functions have been assumed to be positive. Accordingly, it follows that Eq. (5.14) is valid only for the small region

$$\{(k,l,m,n)\,|\,k,l,m,n > -1+\varepsilon,\ -2+2\varepsilon < k+l < -1+2\varepsilon\}\,. \tag{5.15}$$

In this region, k and l can never be integers, and m and n can be only natural numbers including 0. In order that k, l, m and n can be integers, now we perform an analytic continuation of Eq. (5.14) by using the formula [37]

$$\mathit{\Gamma}(-n \pm \varepsilon) = \frac{(-1)^n}{n!}\left[\pm\frac{1}{\varepsilon} + \psi_1(n+1) + \mathcal{O}(\varepsilon)\right], \quad n \in \mathbb{N}_0\,, \tag{5.16}$$

with $\psi_1(n+1) := \sum_{p=1}^{n} p^{-1} - \gamma$.[6] Here, γ is the Euler-Mascheroni constant. Applying Eq. (5.16) to the denominator of Eq. (5.14), we can simplify Eq. (5.14) as

$$\begin{aligned}
&\langle \mathit{\Phi}_{k,l,m,n} | \mathit{\Phi}_{k',l',m',n'} \rangle \\
&= 2(4\pi)^4(-1)^{k+l}|C_{k,l,m,n}|^2 \delta_{kk'}\delta_{ll'}\delta_{mm'}\delta_{nn'} \\
&\quad \times \lim_{\varepsilon\to+0} \varepsilon^2 \mathit{\Gamma}(k+1-\varepsilon)\mathit{\Gamma}(l+1-\varepsilon)\mathit{\Gamma}(m+1-\varepsilon)\mathit{\Gamma}(n+1-\varepsilon)\,.
\end{aligned} \tag{5.17}$$

Then, by applying Eq. (5.16) to Eq. (5.17), it becomes possible to evaluate $\langle \mathit{\Phi}_{k,l,m,n} | \mathit{\Phi}_{k',l',m',n'} \rangle$ when some or all of k, l, m and n are negative integers. Obviously, the orthogonality condition for the eigenfunctions $\mathit{\Phi}_{k,l,m,n}$ is fulfilled in Eq. (5.17).

Now, we focus our attention on the cases in which two of the four powers k, l, m and n of the twistor function $f_{k,l,m,n}$ take negative integer values, while the other two take non-negative integer values. These cases are especially important in the practical sense that the Penrose transform of such a twistor function yields a massless field in $\mathbb{C}\mathbf{M}$ that is referred to in the literature on twistor theory as an elementary state [2, 23, 27–29]. Also, twistor functions of this form fit well into the framework of twistor diagrams [2, 23, 27–29]. Before evaluating $\langle \mathit{\Phi}_{k,l,m,n} | \mathit{\Phi}_{k',l',m',n'} \rangle$, we note that the combination of gamma functions in Eq. (5.14) is unchanged under the interchange of k and l and under that of m and n. This interchange symmetry originates in the fact that α^0 and α^1 have been assigned the same metric signature "+", while α^2 and α^3 have been assigned the same metric signature "−" (as seen from the definition of $\|\alpha\|^2$ given under Eq. (3.8)). By virtue of the interchange symmetry, it is sufficient for the moment if the following three of the possible six cases are investigated: (a) $k, l \in \mathbb{Z}^-$, $m, n \in \mathbb{N}_0$, (b) $k, l \in \mathbb{N}_0$, $m, n \in \mathbb{Z}^-$, and (c1) $k, n \in \mathbb{Z}^-$, $l, m \in \mathbb{N}_0$. The remaining three cases, that is, (c2) $l, m \in \mathbb{Z}^-$, $k, n \in \mathbb{N}_0$, (c3) $k, m \in \mathbb{Z}^-$, $l, n \in \mathbb{N}_0$, and (c4) $l, n \in \mathbb{Z}^-$, $k, m \in \mathbb{N}_0$, can be immediately found from the case (c1) by the interchange of k and l and/or that of m and n. It should be stressed here that in all of the six cases, the helicity eigenvalue s can take an arbitrary integer or half-integer value. In the following, we examine Eq. (5.17) in each of the cases (a), (b) and (c1) individually.

---

[6] We can also perform an analytic continuation of Eq. (5.14) by using the reflection formula $\mathit{\Gamma}(x)\mathit{\Gamma}(1-x) = \pi/\sin\pi x$ ($x \in \mathbb{C}\setminus\mathbb{Z}$). This analytic continuation leads to the same results as those obtained by using Eq. (5.16).

5.1. Case (a)

In this case, k, l, m and n take the values

$$k, l = -1, -2, -3, \cdots, \quad m, n = 0, 1, 2, \cdots . \tag{5.18}$$

Applying Eq. (5.16) to $\mathit{\Gamma}(k+1-\varepsilon)$ and $\mathit{\Gamma}(l+1-\varepsilon)$ contained in Eq. (5.17), we have

$$\begin{aligned} &\langle \mathit{\Phi}_{k,l,m,n} | \mathit{\Phi}_{k',l',m',n'} \rangle \\ &\quad = 2(4\pi)^4 |C_{k,l,m,n}|^2 \delta_{kk'} \delta_{ll'} \delta_{mm'} \delta_{nn'} \frac{m!n!}{(-k-1)!(-l-1)!} . \end{aligned} \tag{5.19}$$

By choosing $C_{k,l,m,n}$ to be

$$C_{k,l,m,n} = \frac{1}{(4\pi)^2} \sqrt{\frac{(-k-1)!(-l-1)!}{2m!n!}} , \tag{5.20}$$

the eigenfunction $\mathit{\Phi}_{k,l,m,n}$ is normalized to unity and Eq. (5.19) reduces to the orthonormality condition

$$\langle \mathit{\Phi}_{k,l,m,n} | \mathit{\Phi}_{k',l',m',n'} \rangle = \delta_{kk'} \delta_{ll'} \delta_{mm'} \delta_{nn'} . \tag{5.21}$$

5.2. Case (b)

In this case, k, l, m and n take the values

$$k, l = 0, 1, 2, \cdots, \quad m, n = -1, -2, -3, \cdots . \tag{5.22}$$

Applying Eq. (5.16) to $\varGamma(m+1-\varepsilon)$ and $\varGamma(n+1-\varepsilon)$ contained in Eq. (5.17) and using Eq. (4.6), we have

$$\begin{aligned}&\langle \varPhi_{k,l,m,n}|\varPhi_{k',l',m',n'}\rangle \\ &\quad = 2(4\pi)^4|C_{k,l,m,n}|^2\delta_{kk'}\delta_{ll'}\delta_{mm'}\delta_{nn'}\frac{(-1)^{2s}k!l!}{(-m-1)!(-n-1)!}\,. \end{aligned} \tag{5.23}$$

By choosing $C_{k,l,m,n}$ to be

$$C_{k,l,m,n} = \frac{1}{(4\pi)^2}\sqrt{\frac{(-m-1)!(-n-1)!}{2k!l!}}\,, \tag{5.24}$$

Eq. (5.23) reduces to the indefinite orthonormality condition

$$\langle \varPhi_{k,l,m,n}|\varPhi_{k',l',m',n'}\rangle = (-1)^{2s}\delta_{kk'}\delta_{ll'}\delta_{mm'}\delta_{nn'}\,. \tag{5.25}$$

Thus, $\varPhi_{k,l,m,n}$ is normalized to 1 or -1 according to whether the helicity eigenvalue s is integer or half-integer.

5.3. Case (c1)

In this case, k, l, m and n take the values

$$k, n = -1, -2, -3, \cdots\,, \quad l, m = 0, 1, 2, \cdots\,. \tag{5.26}$$

Applying Eq. (5.16) to $\varGamma(k+1-\varepsilon)$ and $\varGamma(n+1-\varepsilon)$ contained in Eq. (5.17), we have

$$\begin{aligned}&\langle \varPhi_{k,l,m,n}|\varPhi_{k',l',m',n'}\rangle \\ &\quad = 2(4\pi)^4|C_{k,l,m,n}|^2\delta_{kk'}\delta_{ll'}\delta_{mm'}\delta_{nn'}\frac{(-1)^{l-n}l!m!}{(-k-1)!(-n-1)!}\,. \end{aligned} \tag{5.27}$$

By choosing $C_{k,l,m,n}$ to be

$$C_{k,l,m,n} = \frac{1}{(4\pi)^2}\sqrt{\frac{(-k-1)!(-n-1)!}{2l!m!}}\,, \tag{5.28}$$

Eq. (5.27) reduces to the indefinite orthonormality condition

$$\langle \varPhi_{k,l,m,n}|\varPhi_{k',l',m',n'}\rangle = (-1)^{l-n}\delta_{kk'}\delta_{ll'}\delta_{mm'}\delta_{nn'}\,. \tag{5.29}$$

In this case, $\varPhi_{k,l,m,n}$ is normalized to 1 or -1 according to the values of l and n, even if the value of s is fixed. It is now clear that the eigenfunctions $\varPhi_{k,l,m,n}$ in the cases (c2), (c3) and (c4) are also normalized to 1 or -1.

6. (Pre-)Hilbert spaces in twistor quantization

In this section, we provide (pre-)Hilbert spaces valid for each of the cases (a), (b) and (ci) ($i = 1, 2, 3, 4$). These spaces are function spaces consisting of linear combinations of $\mathit{\Phi}_{k,l,m,n}$ defined on $\mathbf{T}^{+}$. We also verify that $\hat{\bar{a}}^{\dot{A}}$ is represented in the (pre-)Hilbert spaces as the adjoint operator of $\hat{a}^{A}$.

6.1. Case (a)

In the case (a), we consider the linear combination

$$\mathit{\Phi}^{(a)}(\alpha) := \sum_{k,l\in\mathbb{Z}^{-},\, m,n\in\mathbb{N}_0} c_{k,l,m,n}\mathit{\Phi}_{k,l,m,n}(\alpha)\,, \quad c_{k,l,m,n} \in \mathbb{C}\,. \tag{6.1}$$

Then, as a set of functions of this form, we define the normed linear space

$$\mathsf{H}^{(a)} := \left\{ \mathit{\Phi}^{(a)}(\alpha) \,\middle|\, \langle \mathit{\Phi}^{(a)} | \mathit{\Phi}^{(a)} \rangle = \sum_{k,l\in\mathbb{Z}^{-},\, m,n\in\mathbb{N}_0} |c_{k,l,m,n}|^2 < \infty \right\} \tag{6.2}$$

so as to be consistent with the orthonormality condition (5.21). Using the inequality $|z_1 + z_2|^2 \leq 2(|z_1|^2 + |z_2|^2)$ $(z_1, z_2 \in \mathbb{C})$, we can show for all $\mathit{\Phi}_1^{(a)}, \mathit{\Phi}_2^{(a)} \in \mathsf{H}^{(a)}$ and for all $c_1, c_2 \in \mathbb{C}$ that $c_1\mathit{\Phi}_1^{(a)} + c_2\mathit{\Phi}_2^{(a)} \in \mathsf{H}^{(a)}$. Also, using $|z_1 z_2| \leq \frac{1}{2}(|z_1|^2 + |z_2|^2)$, it is readily seen that the inner product $\langle \mathit{\Psi}^{(a)} | \mathit{\Phi}^{(a)} \rangle = \sum_{k,l\in\mathbb{Z}^{-},\, m,n\in\mathbb{N}_0} \overline{b_{k,l,m,n}}\, c_{k,l,m,n}$ is well-defined. Here, the $b_{k,l,m,n} \in \mathbb{C}$ are coefficients of $\mathit{\Psi}^{(a)} \in \mathsf{H}^{(a)}$. Evidently $\overline{\langle \mathit{\Psi}^{(a)} | \mathit{\Phi}^{(a)} \rangle} = \langle \mathit{\Phi}^{(a)} | \mathit{\Psi}^{(a)} \rangle$ and $\langle \mathit{\Psi}^{(a)} | c_1\mathit{\Phi}_1^{(a)} + c_2\mathit{\Phi}_2^{(a)} \rangle = c_1 \langle \mathit{\Psi}^{(a)} | \mathit{\Phi}_1^{(a)} \rangle + c_2 \langle \mathit{\Psi}^{(a)} | \mathit{\Psi}_2^{(a)} \rangle$ are satisfied. Furthermore, we can prove the completeness of $\mathsf{H}^{(a)}$ with respect to the norm $\sqrt{\langle \mathit{\Phi}^{(a)} | \mathit{\Phi}^{(a)} \rangle}$, which vanishes if and only if $\mathit{\Phi}^{(a)} = 0$. In this way, $\mathsf{H}^{(a)}$ is established as a Hilbert space.

Application of the operators $\hat{a}^{A}$ to $\mathit{\Phi}^{(a)}$ can be evaluated by using Eqs. (4.12) and (5.20) as

$$\langle \bar{\alpha} | \hat{a}^0 | \mathit{\Phi}^{(a)} \rangle = \sum_{k,l\in\mathbb{Z}^{-},\, m,n\in\mathbb{N}_0} \sqrt{-k}\, c_{k-1,l,m,n}\mathit{\Phi}_{k,l,m,n}(\alpha)\,, \tag{6.3a}$$

$$\langle \bar{\alpha} | \hat{a}^1 | \mathit{\Phi}^{(a)} \rangle = \sum_{k,l\in\mathbb{Z}^{-},\, m,n\in\mathbb{N}_0} \sqrt{-l}\, c_{k,l-1,m,n}\mathit{\Phi}_{k,l,m,n}(\alpha)\,, \tag{6.3b}$$

$$\langle \bar{\alpha} | \hat{a}^2 | \mathit{\Phi}^{(a)} \rangle = \sum_{k,l\in\mathbb{Z}^{-},\, m,n\in\mathbb{N}_0} \sqrt{m}\, c_{k,l,m-1,n}\mathit{\Phi}_{k,l,m,n}(\alpha)\,, \tag{6.3c}$$

$$\langle \bar{\alpha} | \hat{a}^3 | \mathit{\Phi}^{(a)} \rangle = \sum_{k,l\in\mathbb{Z}^{-},\, m,n\in\mathbb{N}_0} \sqrt{n}\, c_{k,l,m,n-1}\mathit{\Phi}_{k,l,m,n}(\alpha)\,. \tag{6.3d}$$

Here, it should be noted that $\langle\bar{\alpha}|\hat{a}^0|\mathit{\Phi}_{-1,l,m,n}\rangle = \langle\bar{\alpha}|\hat{a}^1|\mathit{\Phi}_{k,-1,m,n}\rangle = 0$. Because each of the $\langle\bar{\alpha}|\hat{a}^A|\mathit{\Phi}^{(a)}\rangle$ is expressed as a linear combination of the basis functions $\{\mathit{\Phi}_{k,l,m,n}\}_{k,l\in\mathbb{Z}^-,\,m,n\in\mathbb{N}_0}$ of $\mathsf{H}^{(a)}$, it follows that the domain of $\hat{a}^A$, denoted by $\mathsf{D}^{(a)}(\hat{a}^A)$, is a linear subspace of $\mathsf{H}^{(a)}$. For example, $\mathsf{D}^{(a)}(\hat{a}^0)$ is given by $\mathsf{D}^{(a)}(\hat{a}^0) := \big\{\mathit{\Phi}^{(a)}(\alpha) \in \mathsf{H}^{(a)} \big| \sum_{k,l\in\mathbb{Z}^-,\,m,n\in\mathbb{N}_0}(-k)|c_{k,l,m,n}|^2 < \infty\big\}$. Using Eqs. (4.12a) and (5.20), we see that $|\langle\bar{\alpha}|\hat{a}^0|\mathit{\Phi}_{k,l,m,n}\rangle|^2 = -k-1 \to \infty$ as $k \to -\infty$. This implies that $\hat{a}^0$ is an unbounded operator [38–40], and hence it cannot be defined on the whole of $\mathsf{H}^{(a)}$. In a similar manner, we can show that the remaining operators $\hat{a}^A$ $(A = 1, 2, 3)$ are also unbounded; hence, they cannot also be defined on the whole of $\mathsf{H}^{(a)}$. We therefore need to treat $\hat{a}^A$ as a well-defined operator on the subspace $\mathsf{D}^{(a)}(\hat{a}^A) \subset \mathsf{H}^{(a)}$, not on the whole Hilbert space $\mathsf{H}^{(a)}$. It is not difficult to prove that $\mathsf{D}^{(a)}(\hat{a}^A)$ is dense (in $\mathsf{H}^{(a)}$) [38–40]; that is, an arbitrary element of $\mathsf{H}^{(a)}$ can be approximated by an element of $\mathsf{D}^{(a)}(\hat{a}^A)$ to any level of accuracy.

Application of the operators $\hat{\bar{a}}^{\dot{A}}$ to $\mathit{\Phi}^{(a)}$ can be evaluated by using Eqs. (4.13) and (5.20) as follows:

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{0}}|\mathit{\Phi}^{(a)}\rangle = \sum_{k,l\in\mathbb{Z}^-,\,m,n\in\mathbb{N}_0} \sqrt{-k-1}\, c_{k+1,l,m,n}\mathit{\Phi}_{k,l,m,n}(\alpha)\,, \tag{6.4a}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{1}}|\mathit{\Phi}^{(a)}\rangle = \sum_{k,l\in\mathbb{Z}^-,\,m,n\in\mathbb{N}_0} \sqrt{-l-1}\, c_{k,l+1,m,n}\mathit{\Phi}_{k,l,m,n}(\alpha)\,, \tag{6.4b}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{2}}|\mathit{\Phi}^{(a)}\rangle = \sum_{k,l\in\mathbb{Z}^-,\,m,n\in\mathbb{N}_0} \sqrt{m+1}\, c_{k,l,m+1,n}\mathit{\Phi}_{k,l,m,n}(\alpha)\,, \tag{6.4c}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{3}}|\mathit{\Phi}^{(a)}\rangle = \sum_{k,l\in\mathbb{Z}^-,\,m,n\in\mathbb{N}_0} \sqrt{n+1}\, c_{k,l,m,n+1}\mathit{\Phi}_{k,l,m,n}(\alpha)\,. \tag{6.4d}$$

Here, we should note that $\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{2}}|\mathit{\Phi}_{k,l,0,n}\rangle = \langle\bar{\alpha}|\hat{\bar{a}}^{\dot{3}}|\mathit{\Phi}_{k,l,m,0}\rangle = 0$. It is clear from Eq. (6.4) that the domain of each $\hat{\bar{a}}^{\dot{A}}$, denoted by $\mathsf{D}^{(a)}(\hat{\bar{a}}^{\dot{A}})$, is a linear subspace of $\mathsf{H}^{(a)}$. As easily seen, $\mathsf{D}^{(a)}(\hat{\bar{a}}^{\dot{A}})$ is identical to $\mathsf{D}^{(a)}(\hat{a}^A)$, i.e., $\mathsf{D}^{(a)}(\hat{\bar{a}}^{\dot{A}}) = \mathsf{D}^{(a)}(\hat{a}^A)$. In common with $\hat{a}^A$, the operator $\hat{\bar{a}}^{\dot{A}}$ is unbounded and hence is treated as a well-defined operator on the subspace $\mathsf{D}^{(a)}(\hat{a}^A)$, not on the whole of $\mathsf{H}^{(a)}$. Since we treat all the operators $\hat{a}^A$ and $\hat{\bar{a}}^{\dot{A}}$ simultaneously, we have to consider the domain $\mathsf{D}^{(a)} := \bigcap_{A=0}^{3}\mathsf{D}^{(a)}(\hat{a}^A)$ common to these operators. Evidently $\mathsf{D}^{(a)}$ is dense (in $\mathsf{H}^{(a)}$).

Using Eqs. (6.3a) and (5.21), we can show that

$$\begin{aligned}\langle \varPsi^{(a)} | \hat{a}^{0} | \varPhi^{(a)} \rangle &= \sum_{\substack{k',l',k,l\in\mathbb{Z}^{-} \\ m',n',m,n\in\mathbb{N}_0}} \overline{b_{k',l',m',n'}} \sqrt{-k}\, c_{k-1,l,m,n} \langle \varPhi_{k',l',m',n'} | \varPhi_{k,l,m,n} \rangle \\ &= \sum_{k,l\in\mathbb{Z}^{-},\, m,n\in\mathbb{N}_0} \sqrt{-k}\, \overline{b_{k,l,m,n}}\, c_{k-1,l,m,n} \,. \end{aligned} \tag{6.5}$$

Also, using Eqs. (6.4a) and (5.21), we have

$$\begin{aligned}\langle \varPhi^{(a)} | \hat{\bar{a}}^{\dot{0}} | \varPsi^{(a)} \rangle &= \sum_{\substack{k',l',k,l\in\mathbb{Z}^{-} \\ m',n',m,n\in\mathbb{N}_0}} \overline{c_{k',l',m',n'}} \sqrt{-k-1}\, b_{k+1,l,m,n} \langle \varPhi_{k',l',m',n'} | \varPhi_{k,l,m,n} \rangle \\ &= \sum_{k,l\in\mathbb{Z}^{-},\, m,n\in\mathbb{N}_0} \sqrt{-k}\, \overline{c_{k-1,l,m,n}}\, b_{k,l,m,n} \,. \end{aligned} \tag{6.6}$$

Then, it is obvious that $\overline{\langle \varPsi^{(a)} | \hat{a}^{0} | \varPhi^{(a)} \rangle} = \langle \varPhi^{(a)} | \hat{\bar{a}}^{\dot{0}} | \varPsi^{(a)} \rangle$. In addition to this, similar relations can be found for the remaining operators $\hat{a}^{A}$ and $\hat{\bar{a}}^{\dot{A}}$ ($A = 1, 2, 3$). Thus, for $A = 0, 1, 2, 3$, we have

$$\overline{\langle \varPsi^{(a)} | \hat{a}^{A} | \varPhi^{(a)} \rangle} = \langle \varPhi^{(a)} | \hat{\bar{a}}^{\dot{A}} | \varPsi^{(a)} \rangle \,, \qquad \varPhi^{(a)}, \varPsi^{(a)} \in \mathsf{D}^{(a)}. \tag{6.7}$$

This shows that $\hat{\bar{a}}^{\dot{A}}$ is represented on $\mathsf{D}^{(a)}$ as the adjoint operator of $\hat{a}^{A}$.

6.2. Case (b)

In the case (b), we consider the linear combination

$$\varPhi^{(b)}(\alpha) := \sum_{k,l\in\mathbb{N}_0,\, m,n\in\mathbb{Z}^{-}} c_{k,l,m,n} \varPhi_{k,l,m,n}(\alpha) \,, \quad c_{k,l,m,n} \in \mathbb{C} \,, \tag{6.8}$$

whose norm squared is defined from Eq. (5.25) as

$$\langle \varPhi^{(b)} | \varPhi^{(b)} \rangle = \sum_{k,l\in\mathbb{N}_0,\, m,n\in\mathbb{Z}^{-}} (-1)^{2s} |c_{k,l,m,n}|^{2} \,. \tag{6.9}$$

Obviously this is an indefinite norm squared. Following the case (a), one may naively choose $\mathsf{W}^{(b)} := \left\{ \varPhi^{(b)}(\alpha) \,\middle|\, |\langle \varPhi^{(b)} | \varPhi^{(b)} \rangle| < \infty \right\}$ as an appropriate function space. However, $\mathsf{W}^{(b)}$ is not a linear space, because it does not close under the addition of two arbitrary elements of $\mathsf{W}^{(b)}$. (In fact, we can give the elements $\Phi_1^{(b)}$ and $\Phi_2^{(b)}$ such that $\langle\Phi_1^{(b)}|\Phi_1^{(b)}\rangle = \langle\Phi_2^{(b)}|\Phi_2^{(b)}\rangle = 0$, while $\langle\Phi_1^{(b)} + \Phi_2^{(b)}|\Phi_1^{(b)} + \Phi_2^{(b)}\rangle \to \infty$.) Instead of $\mathsf{W}^{(b)}$, now we consider the function space

$$\begin{aligned}\mathsf{H}'^{(b)} := \bigl\{\Phi^{(b)}(\alpha)\,\big|\,&\exists k_0 \in \mathbb{N}_0, \exists m_0 \in \mathbb{Z}^- \text{ s.t.} \\ &\forall k, l \geq k_0, \forall m, n \leq m_0 \Rightarrow c_{k,l,m,n} = 0\bigr\}\,. \end{aligned} \tag{6.10}$$

This is precisely the set of all possible *finite* linear combinations of the basis functions $\{\Phi_{k,l,m,n}\}_{k,l\in\mathbb{N}_0,\, m,n\in\mathbb{Z}^-}$. Hence, we can simply express $\mathsf{H}'^{(b)}$ as

$$\mathsf{H}'^{(b)} := \left\{\Phi^{(b)}(\alpha)\,\middle|\, \Phi^{(b)}(\alpha) = \sideset{}{'}\sum_{k,l\in\mathbb{N}_0,\, m,n\in\mathbb{Z}^-} c_{k,l,m,n}\Phi_{k,l,m,n}(\alpha)\right\}, \tag{6.11}$$

where $\sum'$ denotes a *finite* sum. Clearly, $\mathsf{H}'^{(b)}$ is a linear space. By equipping $\mathsf{H}'^{(b)}$ with the inner product $\langle\Psi^{(b)}|\Phi^{(b)}\rangle = \sum'_{k,l\in\mathbb{N}_0,\, m,n\in\mathbb{Z}^-}(-1)^{2s}\,\overline{b_{k,l,m,n}}\,c_{k,l,m,n}$ compatible with the norm squared (6.9), $\mathsf{H}'^{(b)}$ is established as an indefinite-metric pre-Hilbert space (or an indefinite inner product space). Here, the $b_{k,l,m,n} \in \mathbb{C}$ are coefficients of $\Psi^{(b)} \in \mathsf{H}'^{(b)}$. To make a scrupulous analysis, we need to consider the Hilbert space that is defined as a completion of $\mathsf{H}'^{(b)}$. However, we cannot define such a Hilbert space by using only the indefinite norm squared (6.9), because this norm squared does not lead to the notions of convergent sequence, Cauchy sequence and completeness. For this reason, we have to make do with $\mathsf{H}'^{(b)}$ for the present to proceed with our investigation in spite of the lack of strictness.[7]

By using Eqs. (4.12) and (5.24), application of the operators $\hat{a}^A$ to $\Phi^{(b)}$

---

[7] In addition to $\langle\Psi^{(b)}|\Phi^{(b)}\rangle$, we can equip $\mathsf{H}'^{(b)}$ with the positive-definite inner product $(\Psi^{(b)}|\Phi^{(b)}) := \langle\Psi^{(b)}|\mathcal{J}^{(b)}|\Phi^{(b)}\rangle = \sum'_{k,l\in\mathbb{N}_0,\, m,n\in\mathbb{Z}^-}\overline{b_{k,l,m,n}}\,c_{k,l,m,n}$, provided that the metric $\mathcal{J}^{(b)}$ defined by $\langle\Phi_{k,l,m,n}|\mathcal{J}^{(b)}|\Phi_{k',l',m',n'}\rangle = (-1)^{2s}\langle\Phi_{k,l,m,n}|\Phi_{k',l',m',n'}\rangle$ is given to $\mathsf{H}'^{(b)}$. The indefinite-metric pre-Hilbert space $\mathsf{H}'^{(b)}$ with $\mathcal{J}^{(b)}$ is recognized as a *Krein space* [41–43]. With the aid of $\mathcal{J}^{(b)}$, we can define a Hilbert space $\mathsf{H}^{(b)}$ as the completion of $\mathsf{H}'^{(b)}$ with respect to the norm $\sqrt{(\Phi^{(b)}|\Phi^{(b)})}$. Then it becomes possible to develop an argument similar to that in the case (a).

can be evaluated as

$$\langle\bar{\alpha}|\hat{a}^{0}|\varPhi^{(b)}\rangle = \sideset{}{'}\sum_{k,l\in\mathbb{N}_0,\,m,n\in\mathbb{Z}^-} \sqrt{k}\,c_{k-1,l,m,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.12a}$$

$$\langle\bar{\alpha}|\hat{a}^{1}|\varPhi^{(b)}\rangle = \sideset{}{'}\sum_{k,l\in\mathbb{N}_0,\,m,n\in\mathbb{Z}^-} \sqrt{l}\,c_{k,l-1,m,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.12b}$$

$$\langle\bar{\alpha}|\hat{a}^{2}|\varPhi^{(b)}\rangle = \sideset{}{'}\sum_{k,l\in\mathbb{N}_0,\,m,n\in\mathbb{Z}^-} \sqrt{-m}\,c_{k,l,m-1,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.12c}$$

$$\langle\bar{\alpha}|\hat{a}^{3}|\varPhi^{(b)}\rangle = \sideset{}{'}\sum_{k,l\in\mathbb{N}_0,\,m,n\in\mathbb{Z}^-} \sqrt{-n}\,c_{k,l,m,n-1}\varPhi_{k,l,m,n}(\alpha)\,. \tag{6.12d}$$

Here, we should note that $\langle\bar{\alpha}|\hat{a}^{2}|\varPhi_{k,l,-1,n}\rangle = \langle\bar{\alpha}|\hat{a}^{3}|\varPhi_{k,l,m,-1}\rangle = 0$. Similarly, using Eqs. (4.13) and (5.24), we obtain

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{0}}|\varPhi^{(b)}\rangle = \sideset{}{'}\sum_{k,l\in\mathbb{N}_0,\,m,n\in\mathbb{Z}^-} (-1)\sqrt{k+1}\,c_{k+1,l,m,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.13a}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{1}}|\varPhi^{(b)}\rangle = \sideset{}{'}\sum_{k,l\in\mathbb{N}_0,\,m,n\in\mathbb{Z}^-} (-1)\sqrt{l+1}\,c_{k,l+1,m,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.13b}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{2}}|\varPhi^{(a)}\rangle = \sideset{}{'}\sum_{k,l\in\mathbb{N}_0,\,m,n\in\mathbb{Z}^-} (-1)\sqrt{-m-1}\,c_{k,l,m+1,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.13c}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{3}}|\varPhi^{(a)}\rangle = \sideset{}{'}\sum_{k,l\in\mathbb{N}_0,\,m,n\in\mathbb{Z}^-} (-1)\sqrt{-n-1}\,c_{k,l,m,n+1}\varPhi_{k,l,m,n}(\alpha)\,. \tag{6.13d}$$

Here, it should be noted that $\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{0}}|\varPhi_{0,l,m,n}\rangle = \langle\bar{\alpha}|\hat{\bar{a}}^{\dot{1}}|\varPhi_{k,0,m,n}\rangle = 0$. As seen from Eqs. (6.12) and (6.13), each of the $\langle\bar{\alpha}|\hat{a}^{A}|\varPhi^{(b)}\rangle$ and $\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{A}}|\varPhi^{(b)}\rangle$ is expressed as a finite linear combination of the basis functions $\{\varPhi_{k,l,m,n}\}_{k,l\in\mathbb{N}_0,\,m,n\in\mathbb{Z}^-}$ of $\mathsf{H}'^{(b)}$. This implies that $\hat{a}^{A}$ and $\hat{\bar{a}}^{\dot{A}}$ are well-defined operators on $\mathsf{H}'^{(b)}$.[8] Also, using Eqs. (6.12) and (6.13), it can be verified that

$$\overline{\langle\varPsi^{(b)}|\hat{a}^{A}|\varPhi^{(b)}\rangle} = \langle\varPhi^{(b)}|\hat{\bar{a}}^{\dot{A}}|\varPsi^{(b)}\rangle\,, \qquad \varPhi^{(b)},\varPsi^{(b)} \in \mathsf{H}'^{(b)}. \tag{6.14}$$

We thus see that $\hat{\bar{a}}^{\dot{A}}$ is represented on $\mathsf{H}'^{(b)}$ as the adjoint operator of $\hat{a}^{A}$.

---

[8] As mentioned in footnote 7, we can define the Hilbert space $\mathsf{H}^{(b)}$ from $\mathsf{H}'^{(b)}$ with the aid of the metric $\mathscr{J}^{(b)}$. Then, $\hat{a}^{A}$ and $\hat{\bar{a}}^{\dot{A}}$ can be treated as well-defined operators on their common domain $\mathsf{D}^{(b)}(\hat{a}^{A}) = \mathsf{D}^{(b)}(\hat{\bar{a}}^{\dot{A}}) \subset \mathsf{H}^{(b)}$, not on the whole of $\mathsf{H}^{(b)}$. Here, for instance, $\mathsf{D}^{(b)}(\hat{a}^{0})$ is given by $\mathsf{D}^{(b)}(\hat{a}^{0}) := \big\{\varPhi^{(b)}(\alpha) \in \mathsf{H}^{(b)} \big|\, \sum_{k,l\in\mathbb{N}_0,\,m,n\in\mathbb{Z}^-} k|c_{k,l,m,n}|^2 < \infty\big\}$.

6.3. Case (*c*1)

In the case (c1), we consider the linear combination

$$\varPhi^{(c1)}(\alpha) := \sum_{k,n\in\mathbb{Z}^-,\,l,m\in\mathbb{N}_0} c_{k,l,m,n}\varPhi_{k,l,m,n}(\alpha)\,, \quad c_{k,l,m,n}\in\mathbb{C}\,, \tag{6.15}$$

whose norm squared is defined from Eq. (5.29) as

$$\langle\varPhi^{(c1)}|\varPhi^{(c1)}\rangle = \sum_{k,n\in\mathbb{Z}^-,\,l,m\in\mathbb{N}_0} (-1)^{l-n}|c_{k,l,m,n}|^2\,. \tag{6.16}$$

This is an indefinite norm squared. Therefore, as in the case (b), we now make do with the pre-Hilbert space

$$\mathsf{H}'^{(c1)} := \left\{\varPhi^{(c1)}(\alpha)\,\middle|\,\varPhi^{(c1)}(\alpha) = {\sum_{k,n\in\mathbb{Z}^-,\,l,m\in\mathbb{N}_0}}' c_{k,l,m,n}\varPhi_{k,l,m,n}(\alpha)\right\} \tag{6.17}$$

equipped with the inner product $\langle\varPsi^{(c1)}|\varPhi^{(c1)}\rangle = {\sum}'_{k,n\in\mathbb{Z}^-,\,l,m\in\mathbb{N}_0}(-1)^{l-n}\,\overline{b_{k,l,m,n}}\,c_{k,l,m,n}$.[9] Here, the $b_{k,l,m,n}\in\mathbb{C}$ are coefficients of $\varPsi^{(c1)}\in\mathsf{H}'^{(c1)}$.

Application of the operators $\hat{a}^A$ to $\varPhi^{(c1)}$ can be evaluated by using Eqs. (4.12) and (5.28) as

$$\langle\bar{\alpha}|\hat{a}^0|\varPhi^{(c1)}\rangle = {\sum_{k,n\in\mathbb{Z}^-,\,l,m\in\mathbb{N}_0}}' \sqrt{-k}\,c_{k-1,l,m,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.18a}$$

$$\langle\bar{\alpha}|\hat{a}^1|\varPhi^{(c1)}\rangle = {\sum_{k,n\in\mathbb{Z}^-,\,l,m\in\mathbb{N}_0}}' \sqrt{l}\,c_{k,l-1,m,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.18b}$$

$$\langle\bar{\alpha}|\hat{a}^2|\varPhi^{(c1)}\rangle = {\sum_{k,n\in\mathbb{Z}^-,\,l,m\in\mathbb{N}_0}}' \sqrt{m}\,c_{k,l,m-1,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.18c}$$

$$\langle\bar{\alpha}|\hat{a}^3|\varPhi^{(c1)}\rangle = {\sum_{k,n\in\mathbb{Z}^-,\,l,m\in\mathbb{N}_0}}' \sqrt{-n}\,c_{k,l,m,n-1}\varPhi_{k,l,m,n}(\alpha)\,. \tag{6.18d}$$

---

[9] In common with the case (b), we can define a Hilbert space $\mathsf{H}^{(c1)}$ as the completion of $\mathsf{H}'^{(c1)}$ with respect to the norm $\sqrt{\langle\varPsi^{(c1)}|\mathcal{J}^{(c1)}|\varPhi^{(c1)}\rangle}$, provided that the metric $\mathcal{J}^{(c1)}$ satisfying $\langle\varPhi_{k,l,m,n}|\mathcal{J}^{(c1)}|\varPhi_{k',l',m',n'}\rangle = (-1)^{l-n}\langle\varPhi_{k,l,m,n}|\varPhi_{k',l',m',n'}\rangle$ is given to $\mathsf{H}'^{(c1)}$.

Here, we should note that $\langle\bar{\alpha}|\hat{a}^0|\varPhi_{-1,l,m,n}\rangle = \langle\bar{\alpha}|\hat{a}^3|\varPhi_{k,l,m,-1}\rangle = 0$. Similarly, using Eqs. (4.13) and (5.28), we have

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{0}}|\varPhi^{(c1)}\rangle = \sideset{}{'}\sum_{k,n\in\mathbb{Z}^-,\, l,m\in\mathbb{N}_0} \sqrt{-k-1}\, c_{k+1,l,m,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.19a}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{1}}|\varPhi^{(c1)}\rangle = \sideset{}{'}\sum_{k,n\in\mathbb{Z}^-,\, l,m\in\mathbb{N}_0} (-1)\sqrt{l+1}\, c_{k,l+1,m,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.19b}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{2}}|\varPhi^{(c1)}\rangle = \sideset{}{'}\sum_{k,n\in\mathbb{Z}^-,\, l,m\in\mathbb{N}_0} \sqrt{m+1}\, c_{k,l,m+1,n}\varPhi_{k,l,m,n}(\alpha)\,, \tag{6.19c}$$

$$\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{3}}|\varPhi^{(c1)}\rangle = \sideset{}{'}\sum_{k,n\in\mathbb{Z}^-,\, l,m\in\mathbb{N}_0} (-1)\sqrt{-n-1}\, c_{k,l,m,n+1}\varPhi_{k,l,m,n}(\alpha)\,. \tag{6.19d}$$

Here, it should be noted that $\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{1}}|\varPhi_{k,0,m,n}\rangle = \langle\bar{\alpha}|\hat{\bar{a}}^{\dot{2}}|\varPhi_{k,l,0,n}\rangle = 0$. As seen from Eqs. (6.18) and (6.19), each of the $\langle\bar{\alpha}|\hat{a}^A|\varPhi^{(c1)}\rangle$ and $\langle\bar{\alpha}|\hat{\bar{a}}^{\dot{A}}|\varPhi^{(c1)}\rangle$ is expressed as a finite linear combination of the basis functions $\{\varPhi_{k,l,m,n}\}_{k,n\in\mathbb{Z}^-,\, l,m\in\mathbb{N}_0}$ of $\mathsf{H}'^{(c1)}$. In this way, $\hat{a}^A$ and $\hat{\bar{a}}^{\dot{A}}$ are verified to be well-defined operators on $\mathsf{H}'^{(c1)}$. By using Eqs. (6.18) and (6.19), it can be proved that

$$\overline{\langle\varPsi^{(c1)}|\hat{a}^A|\varPhi^{(c1)}\rangle} = \langle\varPhi^{(c1)}|\hat{\bar{a}}^{\dot{A}}|\varPsi^{(c1)}\rangle\,, \qquad \varPhi^{(c1)}, \varPsi^{(c1)} \in \mathsf{H}'^{(c1)}. \tag{6.20}$$

We thus see that $\hat{\bar{a}}^{\dot{A}}$ is represented on $\mathsf{H}'^{(c1)}$ as the adjoint operator of $\hat{a}^A$.

The other possible three cases, namely (c2), (c3) and (c4), can be discussed within the framework of the case (c1) by the interchange of k and l and/or that of m and n. The pre-Hilbert spaces for these three cases are found from Eq. (6.17) to be

$$\mathsf{H}'^{(c2)} := \left\{ \varPhi^{(c2)}(\alpha) \,\middle|\, \varPhi^{(c2)}(\alpha) = \sideset{}{'}\sum_{l,m\in\mathbb{Z}^-,\, k,n\in\mathbb{N}_0} c_{k,l,m,n}\varPhi_{k,l,m,n}(\alpha) \right\}, \tag{6.21}$$

$$\mathsf{H}'^{(c3)} := \left\{ \varPhi^{(c3)}(\alpha) \,\middle|\, \varPhi^{(c3)}(\alpha) = \sideset{}{'}\sum_{k,m\in\mathbb{Z}^-,\, l,n\in\mathbb{N}_0} c_{k,l,m,n}\varPhi_{k,l,m,n}(\alpha) \right\}, \tag{6.22}$$

$$\mathsf{H}'^{(c4)} := \left\{ \varPhi^{(c4)}(\alpha) \,\middle|\, \varPhi^{(c4)}(\alpha) = \sideset{}{'}\sum_{l,n\in\mathbb{Z}^-,\, k,m\in\mathbb{N}_0} c_{k,l,m,n}\varPhi_{k,l,m,n}(\alpha) \right\}, \tag{6.23}$$

where each set is equipped with the inner product that is defined from $\langle\varPsi^{(c1)}|\varPhi^{(c1)}\rangle$ by an appropriate permutation of k, l, m and n under the summation symbol $\sum'$. The relation $\overline{\langle\varPsi^{(ci)}|\hat{a}^A|\varPhi^{(ci)}\rangle} = \langle\varPhi^{(ci)}|\hat{\bar{a}}^{\dot{A}}|\varPsi^{(ci)}\rangle$ holds for arbitrary elements $\Phi^{(ci)}$ and $\Psi^{(ci)}$ of $\mathsf{H}'^{(ci)}$ $(i = 2, 3, 4)$. This shows that $\hat{\bar{a}}^{\dot{A}}$ is represented on $\mathsf{H}'^{(ci)}$ as the adjoint operator of $\hat{a}^{A}$.

We have demonstrated that in the spaces $\mathsf{D}^{(a)}$, $\mathsf{H}'^{(b)}$ and $\mathsf{H}'^{(ci)}$, the operator $\hat{\bar{a}}^{\dot{A}}$ is represented as the adjoint operator of $\hat{a}^{A}$. Its proof has been accomplished by basically using Eqs. (3.9a) and (3.9b), via Eqs. (4.12) and (4.13). This fact implies that the operators represented as

$$\hat{a}^{A} \doteq \alpha^{A}\,, \quad \hat{\bar{a}}^{\dot{A}} \doteq -\frac{\partial}{\partial \alpha^{B}} I^{B\dot{A}} + \frac{1}{2}\bar{\alpha}^{\dot{A}} \tag{6.24}$$

are realized in $\mathsf{D}^{(a)}$, $\mathsf{H}'^{(b)}$ and $\mathsf{H}'^{(ci)}$ as an adjoint pair of operators. Correspondingly, the twistor operators represented as

$$\hat{Z}^{A} \doteq Z^{A}\,, \quad \hat{\bar{Z}}_{A} \doteq -\frac{\partial}{\partial Z^{A}} + \frac{1}{2}\bar{Z}_{A} \tag{6.25}$$

are also realized in $\mathsf{D}^{(a)}$, $\mathsf{H}'^{(b)}$ and $\mathsf{H}'^{(ci)}$ as an adjoint pair of operators. If we adopt the twistor functions $\{f_{k,l,m,n}\}$ as basis functions instead of $\{\Phi_{k,l,m,n}\}$, the differential operators

$$\hat{\bar{a}}^{\dot{A}} \doteq -\frac{\partial}{\partial \alpha^{B}} I^{B\dot{A}}\,, \quad \hat{\bar{Z}}_{A} \doteq -\frac{\partial}{\partial Z^{A}} \tag{6.26}$$

are recognized in $\mathsf{D}^{(a)}$, $\mathsf{H}'^{(b)}$ and $\mathsf{H}'^{(ci)}$ as the adjoint operators of $\hat{a}^{A} \doteq \alpha^{A}$ and $\hat{Z}^{A} \doteq Z^{A}$, respectively. Thus, it turns out that the representation (2.4) is valid in $\mathsf{D}^{(a)}$, $\mathsf{H}'^{(b)}$ and $\mathsf{H}'^{(ci)}$, provided $\{f_{k,l,m,n}\}$ are taken to be their basis functions.

Now, let $\circ$ and $\bullet$ be any of the symbols a, b and ci $(i = 1, 2, 3, 4)$. Then, by virtue of the orthogonality condition for the eigenfunctions $\Phi_{k,l,m,n}$, it follows that $\langle \Phi^{(\circ)} | \Phi^{(\bullet)} \rangle = 0$ for $\circ \neq \bullet$. We can therefore consider the direct sum of the (pre-)Hilbert spaces:[10]

$$\mathsf{H}' := \mathsf{H}^{(a)} \oplus \mathsf{H}'^{(b)} \oplus \bigoplus_{i=1}^{4} \mathsf{H}'^{(ci)}. \tag{6.27}$$

---

[10] If the positive-definite inner products are equipped with $\mathsf{H}'^{(b)}$ and $\mathsf{H}'^{(ci)}$ with the aid of the associated metrics $\mathcal{J}^{(b)}$ and $\mathcal{J}^{(ci)}$, we can define the total Hilbert space $\mathsf{H} := \mathsf{H}^{(a)} \oplus \mathsf{H}^{(b)} \oplus \bigoplus_{i=1}^{4} \mathsf{H}^{(ci)}$. This is precisely the completion of H'.

This space contains all the eigenfunctions $\Phi_{k,l,m,n}$ that have two subscript indices being negative integers and have two subscript indices being non-negative integers. The operators $\hat{a}^{A}$ and $\hat{\bar{a}}^{\dot{A}}$ are well-defined on

$$\mathsf{D}' := \mathsf{D}^{(a)} \oplus \mathsf{H}'^{(b)} \oplus \bigoplus_{i=1}^{4} \mathsf{H}'^{(ci)} \tag{6.28}$$

and form an adjoint pair of operators there. Then it follows that the twistor operators represented as Eq. (6.24), or equivalently as Eq. (6.25), form, in D', an adjoint pair of operators. By choosing $\{f_{k,l,m,n}\}$ as basis functions, the twistor operators represented as Eq. (2.4) are recognized in D' as an adjoint pair of operators.

7. Penrose transforms of the simplest twistor functions

In Sections 5 and 6, we have essentially treated the twistor functions $f_{k,l,m,n}$ on $\mathbf{T}^{+}$. The Penrose transforms of these functions yield positive-frequency massless fields in $\mathbb{C}\mathbf{M}$, or in other words, massless fields in the forward tube in $\mathbb{C}\mathbf{M}$:[11]

$$\mathbb{C}\mathbf{M}^{+} := \left\{ (z^{\mu}) \in \mathbb{C}\mathbf{M} \,\middle|\, z^{\mu} = x^{\mu} - iy^{\mu},\ y_{\mu}y^{\mu} > 0,\ y^{0} > 0 \right\}, \tag{7.1}$$

where x^{μ} and y^{μ} ($\mu = 0, 1, 2, 3$) are real numbers, and $y_{\mu}y^{\mu} := (y^{0})^{2} - (y^{1})^{2} - (y^{2})^{2} - (y^{3})^{2}$ [2–6].[12] As is known in twistor theory, a point $z = (z^{\alpha\dot{\alpha}})$ in $\mathbb{C}\mathbf{M}^{+}$ corresponds to the complex projective line

$$\mathbf{L}_{z} := \left\{ [(\alpha^{A})] \in \mathbf{PT} \,\middle|\, \omega^{\alpha} = iz^{\alpha\dot{\alpha}}\pi_{\dot{\alpha}},\ (\pi_{\dot{\alpha}}) \neq 0 \right\} \tag{7.2}$$

lying entirely in $\mathbf{PT}^{+}$. Here, recall that α^{A} and $(\omega^{\alpha}, \pi_{\dot{\alpha}})$ are related by Eq. (3.11). The geometrical relation between $\mathbb{C}\mathbf{M}^{+}$ and $\mathbf{PT}^{+}$ can elegantly be

---

[11] Strictly speaking, the forward and backward tubes are defined in the conformal compactification $\mathbb{C}\mathbf{M}^{\sharp}$ of $\mathbb{C}\mathbf{M}$. In this paper, however, we do not consider the α-planes at infinity, and accordingly we use the (restricted) forward tube defined in Eq. (7.1). This restriction is represented in $\mathbf{T}$ and $\mathbf{PT}$ as the condition $(\pi_{\dot{\alpha}}) \neq 0$.

[12] The bispinor notation $z^{\alpha\dot{\alpha}}$ and the 4-vector notation z^{μ} are related by

$$\begin{pmatrix} z^{0\dot{0}} & z^{0\dot{1}} \\ z^{1\dot{0}} & z^{1\dot{1}} \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} z^{0} + z^{3} & z^{1} + iz^{2} \\ z^{1} - iz^{2} & z^{0} - z^{3} \end{pmatrix}.$$

Note that $z^{\alpha\dot{\alpha}}$ is Hermitian if and only if z^{μ} is real.

formulated in terms of the Klein correspondence [17]. In the following, we actually demonstrate the Penrose transform of the simplest twistor function in each of the cases (a), (b) and (ci) ($i = 1, 2, 3, 4$).

7.1. Case (a)

The simplest twistor function in the case (a) is found from Eqs. (4.5) and (5.20) to be

$$f_{-1,-1,0,0}(\alpha) = \frac{1}{\sqrt{2}(4\pi)^2\alpha^0\alpha^1}\,. \tag{7.3}$$

The singularities of $f_{-1,-1,0,0}$ lie on the two hyperplanes in $\mathbf{T}$ that are specified by $\alpha^0 = 0$ and $\alpha^1 = 0$. These equations define the following two planes in $\mathbf{PT}$:

$$\mathbf{Q}^0 := \bigl\{ [(\alpha^A)] \in \mathbf{PT} \bigm| \alpha^0 = 0 \bigr\}, \quad \mathbf{Q}^1 := \bigl\{ [(\alpha^A)] \in \mathbf{PT} \bigm| \alpha^1 = 0 \bigr\}. \tag{7.4}$$

Obviously, they are not parallel. Recalling Eq. (3.11), we can write the simultaneous equations $\alpha^0 = 0$ and $\alpha^1 = 0$ in terms of the twistor variables $(\omega^\alpha, \pi_{\dot{\alpha}})$ as

$$\omega^\alpha = iu^{\alpha\dot{\alpha}}\pi_{\dot{\alpha}}\,, \quad (u^{\alpha\dot{\alpha}}) := \begin{pmatrix} i & 0 \\ 0 & i \end{pmatrix}. \tag{7.5}$$

With this expression, the intersection of $\mathbf{Q}^0$ and $\mathbf{Q}^1$ can be expressed as [13]

$$\mathbf{L}_u = \bigl\{ [(\alpha^A)] \in \mathbf{PT} \bigm| \omega^\alpha = iu^{\alpha\dot{\alpha}}\pi_{\dot{\alpha}},\, (\pi_{\dot{\alpha}}) \neq 0 \bigr\}. \tag{7.6}$$

This is precisely the complex projective line corresponding to the point $u = (u^{\alpha\dot{\alpha}}) \in \mathbb{C}\mathbf{M}$. Writing $(u^{\alpha\dot{\alpha}})$ as $(u^\mu) = (\sqrt{2}i, 0, 0, 0)$ in 4-vector notation, we immediately see that the point u is in the backward tube in $\mathbb{C}\mathbf{M}$:

$$\mathbb{C}\mathbf{M}^- := \bigl\{ (z^\mu) \in \mathbb{C}\mathbf{M} \bigm| z^\mu = x^\mu - iy^\mu,\, y_\mu y^\mu > 0,\, y^0 < 0 \bigr\}. \tag{7.7}$$

---

[13] Let $\boldsymbol{\mathcal{Q}}^0$ and $\boldsymbol{\mathcal{Q}}^1$ be the hyperplanes in $\mathbf{T}$ that are specified by $\alpha^0 = 0$ and $\alpha^1 = 0$, respectively. The intersection $\boldsymbol{\mathcal{Q}}^0 \cap \boldsymbol{\mathcal{Q}}^1$ contains the origin $\mathbf{0} := (0, 0, 0, 0)$ in $\mathbf{T}$, and therefore $\mathbf{0}$ must be removed from $\boldsymbol{\mathcal{Q}}^0 \cap \boldsymbol{\mathcal{Q}}^1$ to define the intersection of $\mathbf{Q}^0$ and $\mathbf{Q}^1$. In fact, the intersection $\mathbf{Q}^0 \cap \mathbf{Q}^1$ can be written as $\bigl((\boldsymbol{\mathcal{Q}}^0 \cap \boldsymbol{\mathcal{Q}}^1) \setminus \{\mathbf{0}\}\bigr)/\sim$, with the equivalence relation $(\alpha^A) \sim (\upsilon\alpha^A)$ for all $\upsilon \in \mathbb{C} \setminus \{0\}$. The condition $(\pi_{\dot{\alpha}}) \neq 0$ in $\mathbf{L}_u$ is thus necessary to state that $\mathbf{0}$ is removed in defining $\mathbf{Q}^0 \cap \mathbf{Q}^1$.

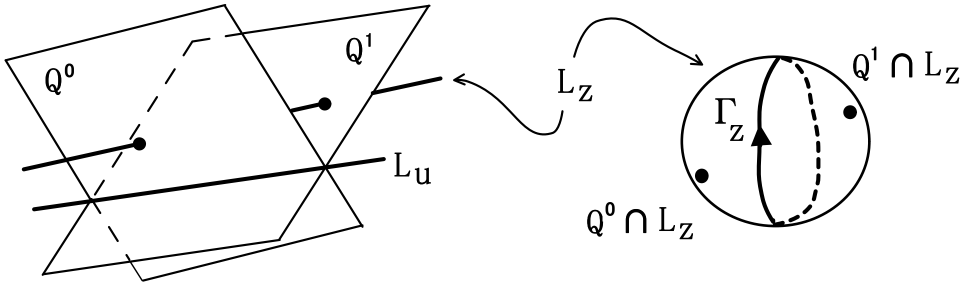

Figure 1: A layout drawing of geometrical objects in the case (a). The planes $\mathbf{Q}^0$ and $\mathbf{Q}^1$ consist of the singularities of $f_{-1,-1,0,0}$ that are evaluated in $\mathbf{PT}$. The complex projective line $\mathbf{L}_z$ is homeomorphic to a sphere S^2, on which the contour $\mathit{\Gamma}_z$ is chosen in such a manner that one of the points $\mathbf{Q}^0 \cap \mathbf{L}_z$ and $\mathbf{Q}^1 \cap \mathbf{L}_z$ lies on either side of $\mathit{\Gamma}_z$.

Just as the forward tube $\mathbb{C}\mathbf{M}^+$ corresponds to $\mathbf{PT}^+$, the backward tube $\mathbb{C}\mathbf{M}^-$ corresponds to $\mathbf{PT}^- := \big\{ [(\alpha^A)] \in \mathbf{PT} \,\big|\, \|\alpha\|^2 < 0 \big\}$. Then, since u is in $\mathbb{C}\mathbf{M}^-$, it follows that $\mathbf{L}_u$ lies entirely in $\mathbf{PT}^-$. In fact, the condition $\|\alpha\|^2 = -|\alpha^2|^2 - |\alpha^3|^2 < 0$ is valid for an arbitrary element of $\mathbf{L}_u$. We thus see that $\mathbf{L}_z$ corresponding to an arbitrary point $z \in \mathbb{C}\mathbf{M}^+$ never meets $\mathbf{L}_u$.

In terms of $z^{\alpha\dot{\alpha}}$, $\pi_{\dot{0}}$ and $\zeta := \pi_{\dot{1}}/\pi_{\dot{0}}$, the twistor function $f_{-1,-1,0,0}$ can be written as

$$\begin{aligned} & f_{-1,-1,0,0}(z, \pi_{\dot{0}}, \zeta) \\ & = \frac{\sqrt{2}}{(4\pi)^2 (\pi_{\dot{0}})^2 i z^{0\dot{1}} (i z^{1\dot{1}} + 1) \left(\zeta + \dfrac{i z^{0\dot{0}} + 1}{i z^{0\dot{1}}} \right) \left(\zeta + \dfrac{i z^{1\dot{0}}}{i z^{1\dot{1}} + 1} \right)} \, . \end{aligned} \tag{7.8}$$

This is a function on $\mathbf{T}^+$, as long as z is a point in $\mathbb{C}\mathbf{M}^+$. The ratio ζ can be regarded as an inhomogeneous coordinate of a point on $\mathbf{L}_z\,(\cong \mathbb{C}\mathbf{P}^1 \cong S^2)$. Although $\mathbf{L}_z$ does not meet $\mathbf{L}_u$, it meets the planes $\mathbf{Q}^0$ and $\mathbf{Q}^1$ at distinct points in $\mathbf{PT}^+$; see Fig. 1. These intersection points, that is, $Q^0 := \mathbf{Q}^0 \cap \mathbf{L}_z$ and $Q^1 := \mathbf{Q}^1 \cap \mathbf{L}_z$ are poles of $f_{-1,-1,0,0}$. Noting this, now we consider the Penrose transform of $f_{-1,-1,0,0}$. Since $f_{-1,-1,0,0}$ is a twistor function of $s = 0$, its Penrose transform is given by

$$\phi^{(a)}(z) := \frac{1}{2\pi i} \oint_{\mathit{\Gamma}_z} f_{-1,-1,0,0}(z, \pi_{\dot{0}}, \zeta) \pi_{\dot{\alpha}} d\pi^{\dot{\alpha}} \, , \tag{7.9}$$

where $\mathit{\Gamma}_z$ denotes a closed contour on $\mathbf{L}_z$. To carry out the contour integration so that it can yield a non-trivial result, we choose $\mathit{\Gamma}_z$ to be a topological circle such that only one of Q^0 and Q^1 lies on either side of $\mathit{\Gamma}_z$. Then, after using $\pi_{\dot{\alpha}} d\pi^{\dot{\alpha}} = (\pi_{\dot{0}})^2 d\zeta$, Cauchy's theorem gives

$$\phi^{(a)}(z) = \frac{1}{4\sqrt{2}\pi^2 (z_\mu - u_\mu)(z^\mu - u^\mu)} \,. \tag{7.10}$$

Here, Q^0 or Q^1 has been chosen as a simple pole surrounded by $\mathit{\Gamma}_z$, and accordingly an appropriate orientation of $\mathit{\Gamma}_z$ has been considered. Because $\mathbf{L}_z$ does not meet $\mathbf{L}_u$, the point z is not null-separated from u; that is, $(z_\mu - u_\mu)(z^\mu - u^\mu) \neq 0$ holds for $z \in \mathbb{C}\mathbf{M}^+$.[14] In this way, $\phi^{(a)}$ is proven to be a regular function on $\mathbb{C}\mathbf{M}^+$. Noting the regularity of $\phi^{(a)}$, we can readily verify by a direct calculation that $\phi^{(a)}$ is a solution of the complexified Klein-Gordon equation $\partial_\mu \partial^\mu \phi(z) = 0$ with $\partial_\mu := \partial / \partial z^\mu$.

More generally, we can perform the Penrose transform of the twistor function

$$f_{k,l,m,n}(\alpha) = C_{k,l,m,n} \frac{(\alpha^2)^m (\alpha^3)^n}{(\alpha^0)^{-k} (\alpha^1)^{-l}} \,, \quad k, l \in \mathbb{Z}^-,\ m, n \in \mathbb{N}_0 \,, \tag{7.11}$$

where $C_{k,l,m,n}$ is given in Eq. (5.20). As is demonstrated in Appendix B, the massless field obtained by this transform takes the form of a sum of monomial functions each of which is proportional to a negative power of $(z_\mu - u_\mu)(z^\mu - u^\mu)$. Then the resulting massless field can be shown to be regular on $\mathbb{C}\mathbf{M}^+$.

7.2. Case (b)

Next we consider the simplest twistor function in the case (b):

$$f_{0,0,-1,-1}(\alpha) = \frac{1}{\sqrt{2}(4\pi)^2 \alpha^2 \alpha^3} \,. \tag{7.12}$$

The singularities of $f_{0,0,-1,-1}$ lie on the two hyperplanes in $\mathbf{T}$ that are specified by $\alpha^2 = 0$ and $\alpha^3 = 0$. These equations define the following non-parallel planes in $\mathbf{PT}$:

$$\mathbf{Q}^2 := \left\{ [(\alpha^A)] \in \mathbf{PT} \,\middle|\, \alpha^2 = 0 \right\}, \quad \mathbf{Q}^3 := \left\{ [(\alpha^A)] \in \mathbf{PT} \,\middle|\, \alpha^3 = 0 \right\}. \tag{7.13}$$

---

[14] The null-separated condition $(z_\mu - z'_\mu)(z^\mu - z'^\mu) = 0$ $(z, z' \in \mathbb{C}\mathbf{M}^\sharp)$ holds if and only if $\mathbf{L}_z \cap \mathbf{L}_{z'} \neq \emptyset$ $(\mathbf{L}_z, \mathbf{L}_{z'} \subset \mathbf{PT})$. This implies that meeting lines in $\mathbf{PT}$ correspond to null-separated points in $\mathbb{C}\mathbf{M}^\sharp$, and vice versa.

We can write the simultaneous equations $\alpha^2 = 0$ and $\alpha^3 = 0$ as

$$\omega^{\alpha} = i v^{\alpha\dot{\alpha}} \pi_{\dot{\alpha}} \,, \qquad (v^{\alpha\dot{\alpha}}) := \begin{pmatrix} -i & 0 \\ 0 & -i \end{pmatrix} . \tag{7.14}$$

The intersection of $\mathbf{Q}^2$ and $\mathbf{Q}^3$ is the complex projective line corresponding to the point $v = (v^{\alpha\dot{\alpha}}) \in \mathbb{C}\mathbf{M}$:

$$\mathbf{L}_v = \left\{ [(\alpha^A)] \in \mathbf{PT} \,\middle|\, \omega^{\alpha} = i v^{\alpha\dot{\alpha}} \pi_{\dot{\alpha}} ,\, (\pi_{\dot{\alpha}}) \neq 0 \right\} . \tag{7.15}$$

Here, the condition $(\pi_{\dot{\alpha}}) \neq 0$ is necessary to state that the origin $\mathbf{0} \in \mathbf{T}$ is removed in defining the intersection $\mathbf{Q}^2 \cap \mathbf{Q}^3$. Writing $(v^{\alpha\dot{\alpha}})$ as $(v^{\mu}) = (-\sqrt{2}i, 0, 0, 0)$ in 4-vector notation, we immediately see that the point v is in the forward tube $\mathbb{C}\mathbf{M}^+$, and hence $\mathbf{L}_v$ lies entirely in $\mathbf{PT}^+$. In fact, the condition $\|\alpha\|^2 = |\alpha^0|^2 + |\alpha^1|^2 > 0$ is valid for an arbitrary element of $\mathbf{L}_v$. For this reason, $\mathbf{L}_z$ ($z \in \mathbb{C}\mathbf{M}^+$) may meet $\mathbf{L}_v$.

In terms of $z^{\alpha\dot{\alpha}}$, $\pi_{\dot{0}}$ and ζ, the twistor function $f_{0,0,-1,-1}$ can be written as

$$\begin{aligned} & f_{0,0,-1,-1}(z, \pi_{\dot{0}}, \zeta) \\ & = \frac{\sqrt{2}}{(4\pi)^2 (\pi_{\dot{0}})^2 (-iz^{0\dot{1}})(-iz^{1\dot{1}} + 1) \left(\zeta + \dfrac{-iz^{0\dot{0}} + 1}{-iz^{0\dot{1}}} \right) \left(\zeta + \dfrac{-iz^{1\dot{0}}}{-iz^{1\dot{1}} + 1} \right)} . \end{aligned} \tag{7.16}$$

Suppose now that $\mathbf{L}_z$ does not meet $\mathbf{L}_v$. Then the intersection points $Q^2 := \mathbf{Q}^2 \cap \mathbf{L}_z$ and $Q^3 := \mathbf{Q}^3 \cap \mathbf{L}_z$ are distinct, being two poles of $f_{0,0,-1,-1}$. To carry out the Penrose transform of $f_{0,0,-1,-1}$, we choose a closed contour $\mathit{\Gamma}_z$ on $\mathbf{L}_z$ in such a manner that only one of Q^2 and Q^3 lies on either side of $\mathit{\Gamma}_z$. Thereby we have

$$\begin{aligned} \phi^{(b)}(z) &:= \frac{1}{2\pi i} \oint_{\mathit{\Gamma}_z} f_{0,0,-1,-1}(z, \pi_{\dot{0}}, \zeta) \pi_{\dot{\alpha}} d\pi^{\dot{\alpha}} \\ &= \frac{1}{4\sqrt{2}\pi^2 (z_{\mu} - v_{\mu})(z^{\mu} - v^{\mu})} \,, \end{aligned} \tag{7.17}$$

where an orientation of $\mathit{\Gamma}_z$ has been taken appropriately in accordance with the choice of a simple pole surrounded by $\mathit{\Gamma}_z$. If $\mathbf{L}_z$ meets $\mathbf{L}_v$, as seen in Fig.

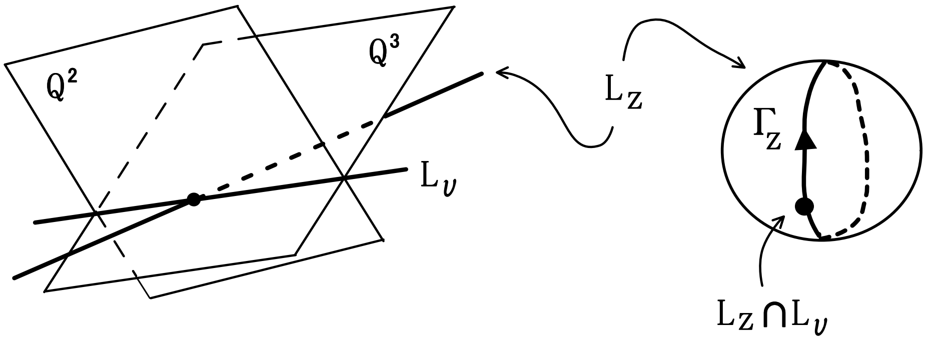

Figure 2: A layout drawing of geometrical objects in an exceptional situation in the case (b). The complex projective line $\mathbf{L}_z$ meets the intersection $\mathbf{L}_v$ of $\mathbf{Q}^2$ and $\mathbf{Q}^3$, and correspondingly the two points $\mathbf{Q}^2 \cap \mathbf{L}_z$ and $\mathbf{Q}^3 \cap \mathbf{L}_z$ on S^2 degenerate into the single point $\mathbf{L}_z \cap \mathbf{L}_v$ on $\mathit{\Gamma}_z$. As a result, the contour integral in Eq. (7.17) becomes ambiguous.

2, then the two points Q^2 and Q^3 degenerate into the single point denoted by $\mathbf{L}_z \cap \mathbf{L}_v$. In this situation, the contour integral in Eq. (7.17) is not well-defined, and correspondingly $\phi^{(b)}$ becomes infinite owing to the fact that z is null-separated from v. Thus, $\phi^{(b)}$ turns out to have singularities in $\mathbb{C}\mathbf{M}^{+}$.

We can also perform the Penrose transform of the twistor function

$$f_{k,l,m,n}(\alpha) = C_{k,l,m,n} \frac{(\alpha^0)^k (\alpha^1)^l}{(\alpha^2)^{-m} (\alpha^3)^{-n}} , \quad k, l \in \mathbb{N}_0,\ m, n \in \mathbb{Z}^{-}, \tag{7.18}$$

where $C_{k,l,m,n}$ is given in Eq. (5.24). The massless field derived by this transform is a sum of monomial functions each of which is proportional to a negative power of $(z_\mu - v_\mu)(z^\mu - v^\mu)$. This implies that the resulting massless field has singularities in $\mathbb{C}\mathbf{M}^{+}$.

7.3. Case (*c*1)

In the case (c1), the simplest twistor function is given by

$$f_{-1,0,0,-1}(\alpha) = \frac{1}{\sqrt{2}(4\pi)^2 \alpha^0 \alpha^3} . \tag{7.19}$$

The singularities of $f_{-1,0,0,-1}$ constitute the planes $\mathbf{Q}^0$ and $\mathbf{Q}^3$ defined in Eqs. (7.4) and (7.13), respectively. These planes are not parallel, so that their intersection can be defined as

$$\mathbf{L}_w = \left\{ [(\alpha^A)] \in \mathbf{PT} \,\middle|\, \omega^\alpha = i w^{\alpha\dot{\alpha}} \pi_{\dot{\alpha}},\, (\pi_{\dot{\alpha}}) \neq 0 \right\}, \tag{7.20}$$

with

$$(w^{\alpha\dot{\alpha}}) := \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}. \tag{7.21}$$

Writing $(w^{\alpha\dot{\alpha}})$ as $(w^\mu) = (0, 0, 0, \sqrt{2}i)$ in 4-vector notation, we see that $\Im w_\mu \Im w^\mu = -2$ for the imaginary part of (w^μ) specified by $w^\mu = \Re w^\mu - i \Im w^\mu$. The imaginary part $(\Im w^\mu)$ is thus shown to be a spacelike vector. Then, it can be proven that $\mathbf{L}_w$ meets all three of $\mathbf{PT}^+$, $\mathbf{PT}^-$ and $\mathbf{PN} := \left\{ [(\alpha^A)] \in \mathbf{PT} \,\middle|\, \|\alpha\|^2 = 0 \right\}$ [3]. This is also understood from the fact that $\|\alpha\|^2$ for an arbitrary element of $\mathbf{L}_w$ takes the indefinite form $|\alpha^1|^2 - |\alpha^2|^2$. In this way, we see that $\mathbf{L}_z$ $(z \in \mathbb{C}\mathbf{M}^+)$ may meet $\mathbf{L}_w$.

In terms of $z^{\alpha\dot{\alpha}}$, $\pi_{\dot{0}}$ and ζ, the twistor function $f_{-1,0,0,-1}$ can be written as

$$\begin{aligned} & f_{-1,0,0,-1}(z, \pi_{\dot{0}}, \zeta) \\ & = \frac{\sqrt{2}}{(4\pi)^2 (\pi_{\dot{0}})^2 i z^{0\dot{1}} (-i z^{1\dot{1}} + 1) \left(\zeta + \dfrac{i z^{0\dot{0}} + 1}{i z^{0\dot{1}}} \right) \left(\zeta + \dfrac{-i z^{1\dot{0}}}{-i z^{1\dot{1}} + 1} \right)} . \end{aligned} \tag{7.22}$$

If $\mathbf{L}_z$ does not meet $\mathbf{L}_w$, then the intersection points Q^0 and Q^3 are distinct, being two poles of $f_{-1,0,0,-1}$. The Penrose transform of $f_{-1,0,0,-1}$ is carried out by choosing a closed contour $\mathit{\Gamma}_z$ such that only one of Q^0 and Q^3 lies on either side of $\mathit{\Gamma}_z$. Using Cauchy's theorem, we have

$$\begin{aligned} \phi^{(c1)}(z) &:= \frac{1}{2\pi i} \oint_{\mathit{\Gamma}_z} f_{-1,0,0,-1}(z, \pi_{\dot{0}}, \zeta) \pi_{\dot{\alpha}} d\pi^{\dot{\alpha}} \\ &= \frac{1}{4\sqrt{2}\pi^2 (z_\mu - w_\mu)(z^\mu - w^\mu)}, \end{aligned} \tag{7.23}$$

where an appropriate orientation of $\mathit{\Gamma}_z$ has been considered. If $\mathbf{L}_z$ meets $\mathbf{L}_w$, then the contour integral in Eq. (7.23) is not well-defined, and correspondingly $\phi^{(c1)}$ becomes infinite. Hence, in common with $\phi^{(b)}$, the field $\phi^{(c1)}$ has singularities in $\mathbb{C}\mathbf{M}^+$.

We can perform the Penrose transform of the twistor function

$$f_{k,l,m,n}(\alpha) = C_{k,l,m,n} \frac{(\alpha^1)^l(\alpha^2)^m}{(\alpha^0)^{-k}(\alpha^3)^{-n}}\,, \quad k, n \in \mathbb{Z}^-,\ l, m \in \mathbb{N}_0\,, \tag{7.24}$$

where $C_{k,l,m,n}$ is given in Eq. (5.28). It turns out that the massless field derived by this transform has singularities in $\mathbb{C}\mathbf{M}^+$ that are specified by $(z_\mu - w_\mu)(z^\mu - w^\mu) = 0$.

7.4. Case (*c*2)

In the case (c2), the simplest twistor function is given by

$$f_{0,-1,-1,0}(\alpha) = \frac{1}{\sqrt{2}(4\pi)^2\alpha^1\alpha^2}\,. \tag{7.25}$$

The singularities of $f_{0,-1,-1,0}$ constitute the non-parallel planes $\mathbf{Q}^1$ and $\mathbf{Q}^2$, whose intersection can be expressed as

$$\mathbf{L}_{-w} = \left\{[(\alpha^A)] \in \mathbf{PT} \,\middle|\, \omega^\alpha = -iw^{\alpha\dot{\alpha}}\pi_{\dot{\alpha}},\, (\pi_{\dot{\alpha}}) \neq 0\right\}, \tag{7.26}$$

with $(w^{\alpha\dot{\alpha}})$ as in Eq. (7.21). Now it is clear that just like $\mathbf{L}_w$ in the case (c1), the line $\mathbf{L}_{-w}$ meets all three of $\mathbf{PT}^+$, $\mathbf{PT}^-$ and $\mathbf{PN}$. In fact, $\|\alpha\|^2$ for an arbitrary element of $\mathbf{L}_{-w}$ takes the indefinite form $|\alpha^0|^2 - |\alpha^3|^2$. For this reason, $\mathbf{L}_z$ ($z \in \mathbb{C}\mathbf{M}^+$) may meet $\mathbf{L}_{-w}$.

If $\mathbf{L}_z$ does not meet $\mathbf{L}_{-w}$, then the intersection points Q^1 and Q^2 are distinct, and the Penrose transform of $f_{0,-1,-1,0}$ can be carried out by choosing a closed contour $\varGamma_z$ and its orientation appropriately:

$$\begin{aligned} \phi^{(c2)}(z) &:= \frac{1}{2\pi i}\oint_{\varGamma_z} f_{0,-1,-1,0}(z, \pi_{\dot{0}}, \zeta)\pi_{\dot{\alpha}}d\pi^{\dot{\alpha}} \\ &= \frac{1}{4\sqrt{2}\pi^2(z_\mu + w_\mu)(z^\mu + w^\mu)}\,. \end{aligned} \tag{7.27}$$

If $\mathbf{L}_z$ meets $\mathbf{L}_{-w}$, then the contour integral in Eq. (7.27) is not well-defined, and correspondingly $\phi^{(c2)}$ becomes infinite. Hence, $\phi^{(c2)}$ also has singularities in $\mathbb{C}\mathbf{M}^+$.

We can also show that the Penrose transform of $f_{k,l,m,n}$ in the case (c2) yields a massless field possessing singularities in $\mathbb{C}\mathbf{M}^+$ that are specified by $(z_\mu + w_\mu)(z^\mu + w^\mu)$=0.

7.5. Case (*c*3)

In the case (c3), the simplest twistor function is given by

$$f_{-1,0,-1,0}(\alpha) = \frac{1}{\sqrt{2}(4\pi)^2\alpha^0\alpha^2}\,. \tag{7.28}$$

The singularities of $f_{-1,0,-1,0}$ constitute the non-parallel planes $\mathbf{Q}^0$ and $\mathbf{Q}^2$. Using Eq. (3.11), we see that $\alpha^0 = \alpha^2 = 0$ is equivalent to $\omega^0 = \pi_{\dot{0}} = 0$. Then the intersection of $\mathbf{Q}^0$ and $\mathbf{Q}^2$ is found to be

$$\mathbf{L}^{02} := \bigl\{ [0, \omega^1, 0, \pi_{\dot{1}}] \in \mathbf{PT} \,\bigm|\, (\omega^1, \pi_{\dot{1}}) \neq (0, 0) \bigr\}. \tag{7.29}$$

This cannot be regarded as a complex projective line corresponding to a point in $\mathbb{C}\mathbf{M}$, because the relation $\omega^\alpha = i\tilde{w}^{\alpha\dot{\alpha}}\pi_{\dot{\alpha}}$ applied to $\mathbf{L}^{02}$ does not uniquely determine a point $\tilde{w}$ in $\mathbb{C}\mathbf{M}$. More precisely, this relation leaves $\tilde{w}^{0\dot{0}}$ and $\tilde{w}^{1\dot{0}}$ undetermined, whereas it determines $\tilde{w}^{0\dot{1}}$ and $\tilde{w}^{1\dot{1}}$ to be 0 and $-i\omega^1/\pi_{\dot{1}}$, respectively. The norm squared $\|\alpha\|^2$ for an arbitrary element of $\mathbf{L}^{02}$ takes the indefinite form $|\alpha^1|^2 - |\alpha^3|^2$, which fact implies that $\mathbf{L}^{02}$ meets all three of $\mathbf{PT}^+$, $\mathbf{PT}^-$ and $\mathbf{PN}$. For this reason, $\mathbf{L}_z$ ($z \in \mathbb{C}\mathbf{M}^+$) may meet $\mathbf{L}^{02}$.

If $\mathbf{L}_z$ does not meet $\mathbf{L}^{02}$, then the intersection points Q^0 and Q^2 are distinct, and the Penrose transform of $f_{-1,0,-1,0}$ can be carried out by choosing a closed contour $\mathit{\Gamma}_z$ and its orientation appropriately:

$$\begin{aligned} \phi^{(c3)}(z) &:= \frac{1}{2\pi i}\oint_{\mathit{\Gamma}_z} f_{-1,0,-1,0}(z, \pi_{\dot{0}}, \zeta)\pi_{\dot{\alpha}}d\pi^{\dot{\alpha}} \\ &= \frac{1}{\sqrt{2}(4\pi)^2 iz^{0\dot{1}}}\,. \end{aligned} \tag{7.30}$$

Although $\phi^{(c3)}$ has an unusual form, it indeed satisfies the complexified Klein-Gordon equation provided that $z^{0\dot{1}} \neq 0$. If $\mathbf{L}_z$ meets $\mathbf{L}^{02}$, then the contour integral in Eq. (7.30) is not well-defined, and correspondingly $\phi^{(c3)}$ becomes infinite. In fact, $z^{0\dot{1}} = 0$ holds at the points corresponding to $\mathbf{L}_z \cap \mathbf{L}^{02}$. Thus we see that $\phi^{(c3)}$ has singularities in $\mathbb{C}\mathbf{M}^+$.

We can also show that the Penrose transform of $f_{k,l,m,n}$ in the case (c3) yields a massless field possessing singularities in $\mathbb{C}\mathbf{M}^+$ that are specified by $z^{0\dot{1}} = 0$.

7.6. Case (*c*4)

In the case (c4), the simplest twistor function is given by

$$f_{0,-1,0,-1}(\alpha) = \frac{1}{\sqrt{2}(4\pi)^2\alpha^1\alpha^3}\,. \tag{7.31}$$

The singularities of $f_{0,-1,0,-1}$ constitute the non-parallel planes $\mathbf{Q}^1$ and $\mathbf{Q}^3$, whose intersection is found to be

$$\mathbf{L}^{13} = \bigl\{[\omega^0, 0, \pi_{\dot{0}}, 0] \in \mathbf{PT} \bigm| (\omega^0, \pi_{\dot{0}}) \neq (0,0)\bigr\}. \tag{7.32}$$

In common with $\mathbf{L}^{02}$, the intersection $\mathbf{L}^{13}$ cannot be regarded as a complex projective line corresponding to a point in $\mathbb{C}\mathbf{M}$. In the present case, the relation $\omega^\alpha = i\tilde{w}^{\alpha\dot{\alpha}}\pi_{\dot{\alpha}}$ leaves $\tilde{w}^{0\dot{1}}$ and $\tilde{w}^{1\dot{1}}$ undetermined, whereas it determines $\tilde{w}^{1\dot{0}}$ and $\tilde{w}^{0\dot{0}}$ to be 0 and $-i\omega^0/\pi_{\dot{0}}$, respectively. The norm squared $\|\alpha\|^2$ for an arbitrary element of $\mathbf{L}^{13}$ takes the indefinite form $|\alpha^0|^2 - |\alpha^2|^2$, which fact implies that $\mathbf{L}^{13}$ meets all three of $\mathbf{PT}^+$, $\mathbf{PT}^-$ and $\mathbf{PN}$. For this reason, $\mathbf{L}_z$ ($z \in \mathbb{C}\mathbf{M}^+$) may meet $\mathbf{L}^{13}$.

If $\mathbf{L}_z$ does not meet $\mathbf{L}^{13}$, then the intersection points Q^1 and Q^3 are distinct, and the Penrose transform of $f_{0,-1,0,-1}$ can be carried out by choosing a closed contour $\varGamma_z$ and its orientation appropriately:

$$\begin{aligned}\phi^{(c4)}(z) &:= \frac{1}{2\pi i}\oint_{\varGamma_z} f_{0,-1,0,-1}(z, \pi_{\dot{0}}, \zeta)\pi_{\dot{\alpha}}d\pi^{\dot{\alpha}} \\ &= -\frac{1}{\sqrt{2}(4\pi)^2 i z^{1\dot{0}}}\,.\end{aligned} \tag{7.33}$$

It can readily be verified that $\phi^{(c4)}$ satisfies the complexified Klein-Gordon equation provided that $z^{1\dot{0}} \neq 0$. If $\mathbf{L}_z$ meets $\mathbf{L}^{13}$, then the contour integral in Eq. (7.33) is not well-defined, and correspondingly $\phi^{(c4)}$ becomes infinite. In fact, $z^{1\dot{0}} = 0$ holds at the points corresponding to $\mathbf{L}_z \cap \mathbf{L}^{13}$. Thus we see that $\phi^{(c4)}$ has singularities in $\mathbb{C}\mathbf{M}^+$.

We can also show that the Penrose transform of $f_{k,l,m,n}$ in the case (c4) yields a massless field possessing singularities in $\mathbb{C}\mathbf{M}^+$ that are specified by $z^{1\dot{0}} = 0$.

We conclude this section with the following remarks: Recalling the Penrose transforms carried out in this section, we observe that only the twistor functions in the case (a) lead to massless fields without singularities in $\mathbb{C}\mathbf{M}^+$, while the twistor functions in the other cases always lead to massless fields with singularities in $\mathbb{C}\mathbf{M}^{+}$. In this situation, we should consider only the massless fields obtained in the case (a) to be *genuine* positive-frequency massless fields in $\mathbb{C}\mathbf{M}$ [2–5].

8. Summary and discussion

We have accomplished our central goal of finding (pre-)Hilbert spaces in twistor quantization, showing that the twistor operators $\hat{a}^{A}$ and $\hat{\bar{a}}^{\dot{A}}$ (or equivalently, $\hat{Z}^{A}$ and $\hat{\bar{Z}}^{\dot{A}}$) form an adjoint pair of operators in all these spaces. We first provided a coherent state defined as a simultaneous eigenstate of the $\hat{\bar{a}}^{\dot{A}}$ and gave an explicit representation of the twistor operators by choosing the coherent-state vectors $\langle\bar{\alpha}|$, satisfying $\langle\bar{\alpha}|\hat{a}^{A} = \alpha^{A}\langle\bar{\alpha}|$, as basis vectors. Then, solving the helicity eigenvalue equation written in terms of α^{A}, we obtained the eigenfunctions $\mathit{\Phi}_{k,l,m,n}(\alpha)$ of the helicity operator. Also, it was shown that $\mathit{\Phi}_{k,l,m,n}$ are simultaneous eigenfunctions of the Cartan generators of $\mathrm{SU}(2,2)$. This fact made it possible to denote $\mathit{\Phi}_{k,l,m,n}$ as $\mathit{\Phi}_{s,K,L,M}$ using the combination of eigenvalues $(s, K, L, M/\sqrt{2}\,)$.

An appropriate inner product for the helicity eigenfunctions $\mathit{\Phi}_{s,K,L,M}$ was precisely defined as an integral over $S^{1} \times \mathbf{PT}^{+}$ in the case that the twistor functions $f_{s,K,L,M} = \mathit{\Phi}_{s,K,L,M} \exp\bigl(-\frac{1}{2}\|\alpha\|^{2}\bigr)$ are realized as functions on the twistor subspace $\mathbf{T}^{+}$. We performed the integration in the inner product by expressing it in terms of hyperbolic polar-coordinate variables and obtained an expression of the inner product that includes a multiplicative factor consisting of gamma functions (cf. Eq. (5.14)). By analytic continuation of the gamma functions, it became possible to use this expression when some or all of k, l, m and n take negative integer values. We also saw that the orthogonality condition for the eigenfunctions $\mathit{\Phi}_{k,l,m,n}$ is guaranteed with this inner product. In particular, the orthogonality with respect to different helicity eigenvalues is valid for the helicity eigenfunctions with different degrees of homogeneity. We actually examined the inner product in the particular cases in which two of k, l, m and n are negative integers and the other two are non-negative integers. This was done by classifying the permissible combinations of (k, l, m, n) into six cases, namely (a), (b) and (ci) ($i = 1, 2, 3, 4$). It was shown that the eigenfunctions $\mathit{\Phi}_{k,l,m,n}$ in the case (a) are normalized to unity, while $\mathit{\Phi}_{k,l,m,n}$ in the cases (b) and (ci) are normalized to either 1 or -1. As seen from Eq. (4.6), the helicity eigenvalue s can take an arbitrary integer or half-integer value in all the six cases. This is due to the twistor quantization procedure, because the helicity at the classical level, given in Eq. (2.2), can take only positive values when $(Z^A) \in \mathbf{T}^+$.

(Pre-)Hilbert spaces appropriate for twistor quantization were defined in each of the cases (a), (b) and (ci) as function spaces consisting of linear combinations of $\varPhi_{k,l,m,n}$. We found that the linear combinations in the case (a) have positive-definite norm squared, and hence the function space in this case is established as a Hilbert space. In contrast, the linear combinations in the cases (b) and (ci) have indefinite norm squared, and therefore we had to make do with indefinite-metric pre-Hilbert spaces to proceed with our investigation. (As was mentioned in footnotes 7, 9 and 10, it is possible to define Hilbert spaces in the cases (b) and (ci) with the aid of the additional metrics $\mathcal{J}^{(b)}$ and $\mathcal{J}^{(ci)}$). In the case (a), we proved that $\hat{\bar{a}}^{\dot{A}}$ is represented on a linear subspace of the Hilbert space as the adjoint operator of $\hat{a}^A$. In each of the cases (b) and (ci), similar proof was given for $\hat{a}^A$ and $\hat{\bar{a}}^{\dot{A}}$ defined on the corresponding pre-Hilbert space. These results imply that the twistor operators represented as Eq. (6.24), or equivalently as Eq. (6.25), form, on the relevant function spaces, an adjoint pair of operators. Correspondingly, the twistor operators represented as Eq. (2.4) are realized as an adjoint pair of operators by taking the twistor functions $\{f_{k,l,m,n}\}$ as basis functions. Thus, we accomplished our purpose of finding appropriate (pre-)Hilbert spaces in which the representations (6.24), (6.25) and (2.4) hold true.

We also argued the Penrose transforms of twistor functions on $\mathbf{T}^+$ in each of the cases (a), (b) and (ci) and derived the corresponding massless fields in $\mathbb{C}\mathbf{M}^+$. In particular, the Penrose transforms of the simplest twistor functions were demonstrated in detail by examining singularities of these functions closely. (In appendix B, the Penrose transform of a general twistor function in the case (a) is demonstrated.) Then we observed that only the twistor functions in the case (a) lead to massless fields without singularities in $\mathbb{C}\mathbf{M}^+$, while the twistor functions in the other cases lead to massless fields with singularities in $\mathbb{C}\mathbf{M}^+$. We should therefore consider only the massless fields derived in the case (a) to be genuine positive-frequency massless fields. Even if we treat only the case (a), the helicity eigenvalue s can take an arbitrary integer or half-integer value.

It should be emphasized that only in the case (a), we can define a (positive-definite) Hilbert space and also can obtain positive-frequency massless fields without singularities. Although the case (a) has these two remarkable properties, it is not clear at present whether these two are related by some profound reason. It is also not clear whether twistor quantization involves the probabilistic interpretation of twistor (wave) functions. If the probabilistic interpretation is required to twistor quantization, only the case (a) would be allowed. Otherwise, all the cases should be considered on an equal footing, and accordingly the total pre-Hilbert space defined by Eq. (6.27), or its completion defined in footnote 10, may be adopted as a function space appropriate for twistor quantization.

Now, it is still left to investigate whether the inner product defined in this paper reproduces the scalar product of massless fields. This investigation will lead to finding relationship between Penrose's inner product [23] and ours, because Penrose's inner product can be derived from the scalar product of massless fields in $\mathbf{M}$. We hope to clarify this point, together with the above-mentioned unclear points, in the near future.

Finally, we note that the present paper has mainly treated twistor functions on $\mathbf{T}^{+}$ so that positive-frequency massless fields in $\mathbb{C}\mathbf{M}$ can be obtained by the Penrose transform. Of course, it is possible to treat twistor functions on the lower half of twistor space, namely $\mathbf{T}^{-} := \big\{ (\alpha^{A}) \in \mathbf{T} \,\big|\, \|\alpha\|^{2} < 0 \big\}$. The Penrose transforms of such twistor functions yield negative-frequency massless fields in $\mathbb{C}\mathbf{M}$. We can immediately apply the arguments provided in this paper to constructing the (pre-)Hilbert spaces that consist of linear combinations of the helicity eigenfunctions on $\mathbf{T}^{-}$.

The authors would like to thank Kazuo Fujikawa, Shigefumi Naka, Takeshi Nihei and Akitsugu Miwa for their encouragement and useful comments. The work of S. D. is supported in part by Grant-in-Aid for Fundamental Scientific Research from College of Science and Technology, Nihon University.

Appendix A. The Schwinger representation of the SU(2, 2) Lie algebra

In this appendix, we provide the Schwinger representation of the Lie algebra of $\mathrm{SU}(2,2)$, in which $\hat{a}^{A}$ and $\hat{\bar{a}}^{\dot{A}}$ are used as constituent operators.

An orthonormal basis of the $\mathrm{SU}(2,2)$ Lie algebra, or a set of generators of SU(2, 2), is given by

$$\varLambda_1 = \frac{1}{2}\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \qquad \varLambda_2 = \frac{1}{2}\begin{pmatrix} 0 & -i & 0 & 0 \\ i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\varLambda_3 = \frac{1}{2}\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \qquad \varLambda_4 = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix},$$

$$\varLambda_5 = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -i \\ 0 & 0 & i & 0 \end{pmatrix}, \qquad \varLambda_6 = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix},$$

$$\varLambda_7 = \frac{1}{2}\begin{pmatrix} 0 & 0 & i & 0 \\ 0 & 0 & 0 & 0 \\ i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \qquad \varLambda_8 = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & i \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ i & 0 & 0 & 0 \end{pmatrix},$$

$$\varLambda_9 = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & i & 0 \\ 0 & i & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \qquad \varLambda_{10} = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & i \\ 0 & 0 & 0 & 0 \\ 0 & i & 0 & 0 \end{pmatrix},$$

$$\varLambda_{11} = \frac{1}{2}\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \qquad \varLambda_{12} = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix},$$

$$\varLambda_{13} = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \qquad \varLambda_{14} = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix},$$

$$\varLambda_{15} = \frac{1}{2\sqrt{2}}\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}. \tag{A.1}$$

These generators actually satisfy the following two conditions necessary for them to be generators of SU(2, 2): the pseudo-Hermitian condition

$$\Lambda_b{}^{\dagger} = I\Lambda_b I\,, \quad b = 1, 2, \ldots, 15\,, \tag{A.2}$$

with $I := \mathrm{diag}(1, 1, -1, -1)$, and the traceless condition

$$\mathrm{Tr}\Lambda_b = 0\,. \tag{A.3}$$

Also, the generators Λ_b fulfill the orthonormality condition

$$\mathrm{Tr}(\Lambda_b \Lambda_c) = \frac{1}{2}\eta_{bc}\,, \tag{A.4}$$

where $(\eta_{bc}) := \mathrm{diag}(\overbrace{1, \ldots, 1}^{6}, \overbrace{-1, \ldots, -1}^{8}, 1)$. Since SU(2, 2) has rank 3, it possesses 3 diagonal generators, namely Λ_3, Λ_6 and Λ_{15}. These are precisely the Cartan generators of SU(2, 2) in the present matrix representation.

Using the generators Λ_b and the twistor operators $\hat{a}^A$ and $\hat{\bar{a}}^{\dot{A}}$, now we define the operators

$$\hat{\Lambda}_b := \hat{\bar{a}}^{\dot{A}} (\Lambda_b)_{\dot{A}}{}^{\dot{B}} I_{\dot{B}C}\, \hat{a}^C, \tag{A.5}$$

which can be written more precisely as

$$\begin{aligned}
\hat{\Lambda}_1 &= \frac{1}{2}\Big(\hat{\bar{a}}^{\dot{0}}\hat{a}^1 + \hat{\bar{a}}^{\dot{1}}\hat{a}^0\Big)\,, & \hat{\Lambda}_2 &= -\frac{i}{2}\Big(\hat{\bar{a}}^{\dot{0}}\hat{a}^1 - \hat{\bar{a}}^{\dot{1}}\hat{a}^0\Big)\,, \\
\hat{\Lambda}_3 &= \frac{1}{2}\Big(\hat{\bar{a}}^{\dot{0}}\hat{a}^0 - \hat{\bar{a}}^{\dot{1}}\hat{a}^1\Big)\,, & \hat{\Lambda}_4 &= -\frac{1}{2}\Big(\hat{\bar{a}}^{\dot{2}}\hat{a}^3 + \hat{\bar{a}}^{\dot{3}}\hat{a}^2\Big)\,, \\
\hat{\Lambda}_5 &= \frac{i}{2}\Big(\hat{\bar{a}}^{\dot{2}}\hat{a}^3 - \hat{\bar{a}}^{\dot{3}}\hat{a}^2\Big)\,, & \hat{\Lambda}_6 &= -\frac{1}{2}\Big(\hat{\bar{a}}^{\dot{2}}\hat{a}^2 - \hat{\bar{a}}^{\dot{3}}\hat{a}^3\Big)\,, \\
\hat{\Lambda}_7 &= -\frac{i}{2}\Big(\hat{\bar{a}}^{\dot{0}}\hat{a}^2 - \hat{\bar{a}}^{\dot{2}}\hat{a}^0\Big)\,, & \hat{\Lambda}_8 &= -\frac{i}{2}\Big(\hat{\bar{a}}^{\dot{0}}\hat{a}^3 - \hat{\bar{a}}^{\dot{3}}\hat{a}^0\Big)\,, \\
\hat{\Lambda}_9 &= -\frac{i}{2}\Big(\hat{\bar{a}}^{\dot{1}}\hat{a}^2 - \hat{\bar{a}}^{\dot{2}}\hat{a}^1\Big)\,, & \hat{\Lambda}_{10} &= -\frac{i}{2}\Big(\hat{\bar{a}}^{\dot{1}}\hat{a}^3 - \hat{\bar{a}}^{\dot{3}}\hat{a}^1\Big)\,, \\
\hat{\Lambda}_{11} &= -\frac{1}{2}\Big(\hat{\bar{a}}^{\dot{0}}\hat{a}^2 + \hat{\bar{a}}^{\dot{2}}\hat{a}^0\Big)\,, & \hat{\Lambda}_{12} &= -\frac{1}{2}\Big(\hat{\bar{a}}^{\dot{0}}\hat{a}^3 + \hat{\bar{a}}^{\dot{3}}\hat{a}^0\Big)\,, \\
\hat{\Lambda}_{13} &= -\frac{1}{2}\Big(\hat{\bar{a}}^{\dot{1}}\hat{a}^2 + \hat{\bar{a}}^{\dot{2}}\hat{a}^1\Big)\,, & \hat{\Lambda}_{14} &= -\frac{1}{2}\Big(\hat{\bar{a}}^{\dot{1}}\hat{a}^3 + \hat{\bar{a}}^{\dot{3}}\hat{a}^1\Big)\,, \\
\hat{\Lambda}_{15} &= \frac{1}{2\sqrt{2}}\Big(\hat{\bar{a}}^{\dot{0}}\hat{a}^0 + \hat{\bar{a}}^{\dot{1}}\hat{a}^1 + \hat{\bar{a}}^{\dot{2}}\hat{a}^2 + \hat{\bar{a}}^{\dot{3}}\hat{a}^3\Big)\,. & &
\end{aligned} \tag{A.6}$$

Using the commutation relations (3.4a) and (3.4b), together with the commutation relations at the matrix level

$$[\mathit{\Lambda}_b, \mathit{\Lambda}_c] = i f_{bc}{}^{d} \mathit{\Lambda}_d \,, \tag{A.7}$$

we can prove that

$$[\hat{\mathit{\Lambda}}_b, \hat{\mathit{\Lambda}}_c] = i f_{bc}{}^{d} \hat{\mathit{\Lambda}}_d \,. \tag{A.8}$$

Here, the $f_{bc}{}^{d}$ denote the structure constants of the $\mathrm{SU}(2,2)$ Lie algebra. The commutation relations in Eq. (A.8) show that the $\hat{\mathit{\Lambda}}_b$ constitute a basis of the Schwinger representation of the $\mathrm{SU}(2,2)$ Lie algebra. In this way, the Schwinger representation of the $\mathrm{SU}(2,2)$ Lie algebra is established by the use of the Weyl-Heisenberg algebra of indefinite-metric type that is defined by Eq. (3.4).

In the Schwinger representation of the $\mathrm{SU}(2,2)$ Lie algebra, the quadratic Casimir operator is defined by

$$\hat{C} := \hat{\Lambda}_b \eta^{bc} \hat{\Lambda}_c \tag{A.9}$$

with $(\eta^{bc}) := \mathrm{diag}(\overbrace{1, \ldots, 1}^{6}, \overbrace{-1, \ldots, -1}^{8}, 1)$. Substituting Eq. (A.5) into Eq. (A.9) and using Eq. (3.4), we obtain

$$\hat{C} = \frac{3}{2}\big(\hat{s}^2 - 1\big) \,, \tag{A.10}$$

where $\hat{s}$ is the helicity operator given in Eq. (4.1), i.e.,

$$\hat{s} = \frac{1}{2}\Big(\hat{\bar{a}}^{\dot{0}}\hat{a}^0 + \hat{\bar{a}}^{\dot{1}}\hat{a}^1 - \hat{\bar{a}}^{\dot{2}}\hat{a}^2 - \hat{\bar{a}}^{\dot{3}}\hat{a}^3\Big) + 1 \,. \tag{A.11}$$

Because $\hat{s}$ commutes with all the operators $\hat{\mathit{\Lambda}}_b$, it follows that $\hat{C}$ commutes with all of the $\hat{\mathit{\Lambda}}_b$. It is obvious that $\hat{s}$, $\hat{\mathit{\Lambda}}_3$, $\hat{\mathit{\Lambda}}_6$, and $\hat{\mathit{\Lambda}}_{15}$ commute with each other. The operators $\hat{\mathit{\Lambda}}_b$ and $\hat{s}$ constitute a basis of the Schwinger representation of the $\mathrm{U}(2,2)$ Lie algebra.

Appendix B. The Penrose transform of $f_{k,l,m,n}$ in the case (a)

In this appendix, we demonstrate the Penrose transform [2–5] of the following twistor function in the case (a):

$$f_{k,l,m,n}(\alpha) = C_{k,l,m,n} \frac{(\alpha^2)^m (\alpha^3)^n}{(\alpha^0)^{-k} (\alpha^1)^{-l}} \,, \quad k, l \in \mathbb{Z}^-,\ m, n \in \mathbb{N}_0 \,, \tag{B.1}$$

where $C_{k,l,m,n}$ is given in Eq. (5.20). This function can be written, in terms of ω^{α} and $\pi_{\dot\alpha}$, as

$$f_{k,l,m,n}(\omega^{\alpha},\pi_{\dot\alpha}) = C_{k,l,m,n}\frac{2^{s+1}(-\omega^{0}+\pi_{\dot0})^{m}(-\omega^{1}+\pi_{\dot1})^{n}}{(\omega^{0}+\pi_{\dot0})^{-k}(\omega^{1}+\pi_{\dot1})^{-l}}\,, \tag{B.2}$$

or, in terms of $z^{\alpha\dot\alpha}$, $\pi_{\dot0}$ and $\zeta := \pi_{\dot1}/\pi_{\dot0}$, as

$$\begin{aligned} f_{k,l,m,n}(z,\pi_{\dot0},\zeta) &= C_{k,l,m,n}\frac{2^{s+1}(-iz^{0\dot1})^{m}(-iz^{1\dot1}+1)^{n}}{(\pi_{\dot0})^{2s+2}(iz^{0\dot1})^{-k}(iz^{1\dot1}+1)^{-l}} \\ &\quad\times\frac{\left(\zeta+\dfrac{-iz^{0\dot0}+1}{-iz^{0\dot1}}\right)^{m}\left(\zeta+\dfrac{-iz^{1\dot0}}{-iz^{1\dot1}+1}\right)^{n}}{\left(\zeta+\dfrac{iz^{0\dot0}+1}{iz^{0\dot1}}\right)^{-k}\left(\zeta+\dfrac{iz^{1\dot0}}{iz^{1\dot1}+1}\right)^{-l}}\,. \end{aligned} \tag{B.3}$$

Here, Eq. (4.6) has been used. In what follows, we individually perform the Penrose transform of $f_{k,l,m,n}$ in the cases of zero helicity ($s=0$), positive helicity ($s>0$), and negative helicity ($s<0$).

Appendix B.1. Case $s=0$

In this case, the Penrose transform is readily carried out by using Cauchy's theorem:

$$\begin{aligned} \phi^{(a)}_{k,l,m,n}(z) &:= \frac{1}{2\pi i}\oint_{\varGamma_z} f_{k,l,m,n}(z,\pi_{\dot0},\zeta)\pi_{\dot\beta}d\pi^{\dot\beta} \\ &= C_{k,l,m,n}\frac{2(-iz^{0\dot1})^{m}(-iz^{1\dot1}+1)^{n}}{(iz^{0\dot1})^{-k}(iz^{1\dot1}+1)^{-l}}\frac{1}{(-l-1)!} \\ &\quad\times\left(\frac{d}{d\zeta}\right)^{-l-1}\left.\frac{\left(\zeta+\dfrac{-iz^{0\dot0}+1}{-iz^{0\dot1}}\right)^{m}\left(\zeta+\dfrac{-iz^{1\dot0}}{-iz^{1\dot1}+1}\right)^{n}}{\left(\zeta+\dfrac{iz^{0\dot0}+1}{iz^{0\dot1}}\right)^{-k}}\right|_{\zeta=\zeta_1}, \end{aligned} \tag{B.4}$$

where $\zeta_1 := -iz^{1\dot0}/(iz^{1\dot1}+1)$. This expression has been found by choosing the intersection point Q^1 as the only pole surrounded by $\varGamma_z$.

Appendix B.2. Case $s > 0$

In this case, s takes either positive integer or positive half-integer values, and accordingly the Penrose transform of $f_{k,l,m,n}$ is given by

$$\phi^{(a)}_{k,l,m,n;\,\dot\alpha_1\ldots\dot\alpha_{2s}}(z) := \frac{1}{2\pi i}\oint_{\Gamma_z} \pi_{\dot\alpha_1}\cdots\pi_{\dot\alpha_{2s}} f_{k,l,m,n}(z,\pi_{\dot 0},\zeta)\pi_{\dot\beta}d\pi^{\dot\beta}\,. \tag{B.5}$$

Because $\phi^{(a)}_{k,l,m,n;\,\dot\alpha_1\ldots\dot\alpha_{2s}}$ is a totally symmetric spinor of rank $2s$, it is sufficient if we consider the components such that $\dot\alpha_1 = \cdots = \dot\alpha_{2s-r} = \dot 0$ and $\dot\alpha_{2s-r+1} = \cdots = \dot\alpha_{2s} = \dot 1$ $(r = 0, 1, \ldots, 2s)$. The integrand in Eq. (B.5) can explicitly be written as

$$\begin{aligned}
&\pi_{\dot\alpha_1}\cdots\pi_{\dot\alpha_{2s}} f_{k,l,m,n}(z,\pi_{\dot 0},\zeta)\\
&\quad = C_{k,l,m,n}\frac{2^{s+1}\zeta^r(-iz^{0\dot 1})^m(-iz^{1\dot 1}+1)^n}{(\pi_{\dot 0})^2(iz^{0\dot 1})^{-k}(iz^{1\dot 1}+1)^{-l}}\\
&\qquad\times\frac{\left(\zeta+\dfrac{-iz^{0\dot 0}+1}{-iz^{0\dot 1}}\right)^m\left(\zeta+\dfrac{-iz^{1\dot 0}}{-iz^{1\dot 1}+1}\right)^n}{\left(\zeta+\dfrac{iz^{0\dot 0}+1}{iz^{0\dot 1}}\right)^{-k}\left(\zeta+\dfrac{iz^{1\dot 0}}{iz^{1\dot 1}+1}\right)^{-l}}\,.
\end{aligned}\tag{B.6}$$

Then, its contour integration around Q^1 leads to

$$\begin{aligned}
&\phi^{(a)}_{k,l,m,n;\,\dot\alpha_1\ldots\dot\alpha_{2s}}(z)\\
&\quad = C_{k,l,m,n}\frac{2^{s+1}(-iz^{0\dot 1})^m(-iz^{1\dot 1}+1)^n}{(iz^{0\dot 1})^{-k}(iz^{1\dot 1}+1)^{-l}}\frac{1}{(-l-1)!}\\
&\qquad\times\left(\frac{d}{d\zeta}\right)^{-l-1}\left.\frac{\zeta^r\left(\zeta+\dfrac{-iz^{0\dot 0}+1}{-iz^{0\dot 1}}\right)^m\left(\zeta+\dfrac{-iz^{1\dot 0}}{-iz^{1\dot 1}+1}\right)^n}{\left(\zeta+\dfrac{iz^{0\dot 0}+1}{iz^{0\dot 1}}\right)^{-k}}\right|_{\zeta=\zeta_1}\,.
\end{aligned}\tag{B.7}$$

Appendix B.3. Case $s < 0$

In this case, s takes either negative integer or negative half-integer values, and accordingly the Penrose transform of $f_{k,l,m,n}$ is given by

$$\phi^{(a)}_{k,l,m,n;\,\alpha_1\ldots\alpha_{-2s}}(z) := \frac{1}{2\pi i}\oint_{\Gamma_z}\frac{\partial}{\partial\omega^{\alpha_1}}\cdots\frac{\partial}{\partial\omega^{\alpha_{-2s}}} f_{k,l,m,n}(z,\pi_{\dot 0},\zeta)\pi_{\dot\beta}d\pi^{\dot\beta}\,. \tag{B.8}$$

Because $\phi^{(a)}_{k,l,m,n;\alpha_1\ldots\alpha_{-2s}}$ is a totally symmetric spinor of rank $-2s$, it is sufficient if we consider the components such that $\alpha_1=\cdots=\alpha_{-2s-r}=0$ and $\dot\alpha_{-2s-r+1}=\cdots=\dot\alpha_{-2s}=1$ $(r=0,1,\ldots,-2s)$. For our calculation, it is convenient to exploit the formula

$$\left(\frac{\partial}{\partial\omega}\right)^{h}\frac{(-\omega+\pi)^{p}}{(\omega+\pi)^{q}}=(-1)^{h}h!\sum_{\hat\imath=0}^{h}\binom{p}{h-\hat\imath}\binom{q+\hat\imath-1}{\hat\imath}\frac{(-\omega+\pi)^{p-h+\hat\imath}}{(\omega+\pi)^{q+\hat\imath}} \tag{B.9}$$

valid for $h,p\in\mathbb{N}_0$ and $q\in\mathbb{Z}^{+}$. Here

$$\binom{p}{h-\hat\imath}=0 \quad \text{for}\ \ p<h-\hat\imath \tag{B.10}$$

is to be understood. Using Eq. (B.9), we can obtain

$$\begin{aligned}
&\frac{\partial}{\partial\omega^{\alpha_1}}\cdots\frac{\partial}{\partial\omega^{\alpha_{-2s}}}f_{k,l,m,n}(\omega^{\alpha},\pi_{\dot\alpha})\\
&=C_{k,l,m,n}2^{s+1}\left(\frac{\partial}{\partial\omega^{0}}\right)^{-2s-r}\frac{(-\omega^{0}+\pi_{\dot0})^{m}}{(\omega^{0}+\pi_{\dot0})^{-k}}\left(\frac{\partial}{\partial\omega^{1}}\right)^{r}\frac{(-\omega^{1}+\pi_{\dot1})^{n}}{(\omega^{1}+\pi_{\dot1})^{-l}}\\
&=C_{k,l,m,n}2^{s+1}(-1)^{-2s}(-2s-r)!\,r!\\
&\quad\times\sum_{\hat\imath=0}^{-2s-r}\sum_{\hat\jmath=0}^{r}\binom{m}{-2s-r-\hat\imath}\binom{-k+\hat\imath-1}{\hat\imath}\binom{n}{r-\hat\jmath}\binom{-l+\hat\jmath-1}{\hat\jmath}\\
&\quad\times\frac{(-\omega^{0}+\pi_{\dot0})^{m+2s+r+\hat\imath}(-\omega^{1}+\pi_{\dot1})^{n-r+\hat\jmath}}{(\omega^{0}+\pi_{\dot0})^{-k+\hat\imath}(\omega^{1}+\pi_{\dot1})^{-l+\hat\jmath}}\,.
\end{aligned} \tag{B.11}$$

In terms of $z^{\alpha\dot{\alpha}}$, $\pi_{\dot{0}}$ and ζ, Eq. (B.11) can be written as

$$\begin{aligned}
&\frac{\partial}{\partial\omega^{\alpha_1}}\cdots\frac{\partial}{\partial\omega^{\alpha_{-2s}}} f_{k,l,m,n}(z,\pi_{\dot{0}},\zeta) \\
&= C_{k,l,m,n}2^{s+1}(-2s-r)!\,r! \\
&\quad\times \sum_{\hat{\imath}=0}^{-2s-r}\sum_{\hat{\jmath}=0}^{r} \binom{m}{-2s-r-\hat{\imath}}\binom{-k+\hat{\imath}-1}{\hat{\imath}}\binom{n}{r-\hat{\jmath}}\binom{-l+\hat{\jmath}-1}{\hat{\jmath}} \\
&\quad\times \frac{(-1)^{m+r+\hat{\imath}}(iz^{0\dot{1}})^{m+2s+r+k}(-iz^{1\dot{1}}+1)^{n-r+\hat{\jmath}}}{(\pi_{\dot{0}})^2(iz^{1\dot{1}}+1)^{-l+\hat{\jmath}}} \\
&\quad\times \frac{\left(\zeta+\dfrac{-iz^{0\dot{0}}+1}{-iz^{0\dot{1}}}\right)^{m+2s+r+\hat{\imath}}\left(\zeta+\dfrac{-iz^{1\dot{0}}}{-iz^{1\dot{1}}+1}\right)^{n-r+\hat{\jmath}}}{\left(\zeta+\dfrac{iz^{0\dot{0}}+1}{iz^{0\dot{1}}}\right)^{-k+\hat{\imath}}\left(\zeta+\dfrac{iz^{1\dot{0}}}{iz^{1\dot{1}}+1}\right)^{-l+\hat{\jmath}}}. \qquad \text{(B.12)}
\end{aligned}$$

Then, its contour integration around Q^1 leads to

$$\begin{aligned}
&\phi^{(a)}_{k,l,m,n;\,\alpha_1\ldots\alpha_{-2s}}(z) \\
&= C_{k,l,m,n}2^{s+1}(-2s-r)!\,r! \\
&\quad\times \sum_{\hat{\imath}=0}^{-2s-r}\sum_{\hat{\jmath}=0}^{r} \binom{m}{-2s-r-\hat{\imath}}\binom{-k+\hat{\imath}-1}{\hat{\imath}}\binom{n}{r-\hat{\jmath}}\binom{-l+\hat{\jmath}-1}{\hat{\jmath}} \\
&\quad\times \frac{(-1)^{m+r+\hat{\imath}}(iz^{0\dot{1}})^{m+2s+r+k}(-iz^{1\dot{1}}+1)^{n-r+\hat{\jmath}}}{(iz^{1\dot{1}}+1)^{-l+\hat{\jmath}}}\frac{1}{(-l+\hat{\jmath}-1)!} \\
&\quad\times \left(\frac{d}{d\zeta}\right)^{-l+\hat{\jmath}-1} \left.\frac{\left(\zeta+\dfrac{-iz^{0\dot{0}}+1}{-iz^{0\dot{1}}}\right)^{m+2s+r+\hat{\imath}}\left(\zeta+\dfrac{-iz^{1\dot{0}}}{-iz^{1\dot{1}}+1}\right)^{n-r+\hat{\jmath}}}{\left(\zeta+\dfrac{iz^{0\dot{0}}+1}{iz^{0\dot{1}}}\right)^{-k+\hat{\imath}}}\right|_{\zeta=\zeta_1}. \\
&\qquad \text{(B.13)}
\end{aligned}$$

From Eqs. (B.4), (B.7) and (B.13), we see that in the case (a), the massless field obtained by the Penrose transform of any arbitrary $f_{k,l,m,n}$ takes the form of a sum of monomial functions each of which is proportional to a negative power of $(z_\mu - u_\mu)(z^\mu - u^\mu)$. Then it can be shown that the resulting massless field possesses no singularities other than those specified by $(z_\mu - u_\mu)(z^\mu - u^\mu) = 0$. Therefore the massless fields derived here are recognized as a regular function on $\mathbb{C}\mathbf{M}^+$. An analysis similar to what has been done in this appendix can be performed in the cases (b) and (ci). In these cases, it can be shown that the Penrose transform of $f_{k,l,m,n}$ yields a massless field that possesses singularities in $\mathbb{C}\mathbf{M}^+$.
